Design Considerations and Requirements for the Non-Converged Data Center Configuration Pattern 441
Networking 441
Storage 442
Compute 442
Overview 442
Non-Converged Data Center Configuration Scenario Overview 443
Install and configure 445
Step 1: Initial node configuration 446
1.1 Enable BIOS settings required for Hyper-V for SR-IOV 447
1.2 Perform a clean operating system installation 447

1.3 Perform post-installation tasks 447
1.4 Install roles and features using the default settings 447
Step 2: Initial network configuration 448
2.1 Disable unused and disconnected interfaces and rename active connections 448
Step 3: Initial storage configuration 449
3.1 Present all shared storage to relevant nodes 449
3.2 Install and configure MPIO as necessary for multipath scenarios 449
Step 4: Failover cluster setup 449
4.1 Run through the Cluster Validation Wizard 450
4.2 Address any indicated warnings and/or errors 450
4.3 Complete the Create Failover Cluster Wizard 450
4.4 Create the witness disk 451
4.5 Create the virtual machine storage disk 451
4.6 Add the virtual machine storage disk and Witness disk to Cluster Shared Volumes .. 451
4.7 Add folders to the cluster shared volume 452
4.8 Configure Quorum Settings 452
4.9 Configure cluster networks to prioritize traffic 452
Step 5: Configure Hyper-V settings 452
5.1 Create the Hyper-V virtual switch 453
5.2 Change default file locations for virtual machine files 453
Step 6: Cloud validation 454
6.1 Create a new virtual machine 454
6.2 Test network connectivity from the virtual machine 455
6.3 Perform a live migration 455
6.4 Perform a quick migration 455

Building Your Cloud Infrastructure: Converged Data Center with File Server Storage 456
Design Considerations and Requirements for the Converged Data Center with File Server Storage Pattern 456
Networking 456
Storage 457
Compute 457
Overview 458
Install and configure the Converged Data Center with File Server Storage cloud infrastructure 460
Step 1: Initial node configuration 464
1.1 Enable BIOS settings required for Hyper-V on the Nodes in the Hyper-V Cluster 464
1.2 Perform a clean operating system installation on all nodes in the Hyper-V and File Server Clusters 464
1.3 Perform post-installation tasks on all nodes in the Hyper-V and File Server Clusters 464
1.4 Install roles and features using the default settings on the Hyper-V Failover Cluster 465
1.5 Install roles and features using the default settings on the File Server Failover Cluster 466

Step 2: Initial network configuration 466
2.1 Disable unused and disconnected interfaces and rename active connections 467
2.2 Create the infrastructure and the tenant networks NIC teams on each member of the Hyper-V cluster 467
2.3 Create the infrastructure network NIC team on each member of the File Server cluster 468
2.4 Configure QoS settings for infrastructure traffic 469
Step 3: Initial storage configuration 470
3.1 Present all shared storage to relevant nodes 471
3.2 Install and configure MPIO as necessary for multipath scenarios 471
3.3 Wipe, bring online, and initialize all shared disks 471
Step 4: File server failover cluster setup 471
4.1 Run through the Cluster Validation Wizard 472
4.2 Address any indicated warnings and/or errors 472
4.3 Complete the Create Failover Cluster Wizard 472
4.4 Create a cluster storage pool 473
4.5 Create the quorum virtual disk 473
4.6 Create the virtual machine storage virtual disk 474
4.7 Add the virtual machine storage virtual disk to Cluster Shared Volumes 475
4.8 Add folders to the cluster shared volume 475
4.9 Configure Quorum Settings 476
4.10 Add the Scale-Out File Server for Applications Role 476
Step 5: Hyper-V Failover Cluster Setup 476
5.1 Run through the cluster validation wizard 477
5.2 Address any indicated warnings and/or errors 477
5.3 Complete the create cluster wizard 477
5.4 Verify cluster quorum configuration and modify as necessary 478
5.5 Configure Cluster Networks 478
Step 6: Configure Share and Hyper-V settings using a Script 478
6.1 Create Shares and Configure Hyper-V Settings using a Script 479
6.2 Configure Kerberos Constrained Delegation 479
Step 7: Cloud validation 479
7.1 Create the TenentNetSwitch 480
7.2 Create a new virtual machine 480
7.3 Test network connectivity from the virtual machine 481
7.4 Perform a live migration 481
7.5 Perform a quick migration 482

Building Your Cloud Infrastructure: Converged Data Center without Dedicated Storage Nodes 482
Design Considerations and Requirements for the Converged Data Center without Dedicated Storage Node Pattern 483
Networking 483
Storage 483

Compute 483
Overview 484
Install and configure the Converged Data Center without Dedicated Storage Server cloud infrastructure 487
Step 1: Initial node configuration 490
1.1 Add appropriate VLANS to the interface ports on the physical switch 491
1.2 Enable BIOS settings required for Hyper-V 491
1.3 Perform a clean operating system installation 491
1.4 Perform post-installation tasks 491
1.5 Install roles and features using the default settings 492
Step 2: Initial network configuration 493
2.1 Disable unused and disconnected interfaces and rename active connections 493
2.2 Create a converged network adapter team 493
2.3 Create the Hyper-V virtual switch and management virtual network adapter 494
2.4 Rename the management virtual network adapter (optional) 495
2.5 Create additional virtual network adapters and assign VLAN IDs 495
2.6 Rename virtual network adapters (optional) 495
2.7 Assign static IP addresses to the virtual network adapters 496
2.8 Configure QoS for different traffic types and configure the default minimum bandwidth for the switch 496
Step 3: Initial storage configuration 496
3.1 Present all shared storage to relevant nodes 497
3.2 Install and configure MPIO as necessary for multipath scenarios 497
3.3 Wipe, bring online, and initialize all shared disks 497
Step 4: Failover cluster setup 497
4.1 Run through the Cluster Validation Wizard 498
4.2 Address any indicated warnings and/or errors 498
4.3 Complete the Create Failover Cluster Wizard 498
4.4 Create a clustered storage pool 499
4.5 Create the quorum virtual disk 499
4.6 Create the virtual machine storage virtual disk 500
4.7 Add the virtual machine storage virtual disk to Cluster Shared Volumes 501
4.8 Add folders to the cluster shared volume 501
4.9 Configure Quorum Settings 502
4.10 Configure cluster networks to prioritize traffic 502
Step 5: Configure Hyper-V settings 502
5.1 Change default file locations for virtual machine files 502
Step 6: Cloud validation 503
6.1 Create a new virtual machine 503
6.2 Test network connectivity from the virtual machine 504
6.3 Perform a live migration 504
6.4 Perform a quick migration 505

Dynamic Access Control: Scenario Overview 505
In this scenario 505
Dynamic Access Control Content Roadmap 506
See also 514

Scenario: Central Access Policy 514
In this scenario 517
Roles and features included in this scenario 517

Plan for a Central Access Policy Deployment 518
Process to map a business request to a central access policy 519
Understand and translate business intent 519
Express access policy in Windows Server 2012 constructs 519
Determine the user groups, resource properties and claim types 519
Determine the servers where this policy should be applied to 520
Planning Guidelines for Deploying Central Access Policies 520
Using Security Groups for Dynamic Access Control 520
Using security groups to limit access to data 520
Using conditional expressions to reduce complexity of security groups 521
Using User Claims 521
Operations to enable user claims 522
Enable the domain controllers to provide claims and compound authentication on request 522
Considerations for using user claims in the file server discretionary ACLs without using Central Access Policies 523
Using Device Claims and Device Security Groups 523
Considerations for using static device claims 523
Operations to enable device claims 523
Enable the Windows 8 devices in domain to request claims and compound authentication 523
Enable the Windows 8 devices to request claims and compound authentication using custom policy 524
Enable the Windows 8 device to receive compound authentication 524
Configuring central access policies with different options 525
Configuration 1: Domains providing claims and compound authentication have all Windows Server 2012 DCs 525
Configuring forest root DCs 525
Configuring domains which provide claims and compound authentication 525
Configuring devices to request claims and compound authentication 526
Configuring resources to receive compound authentication 526
Configuration 2: Only user claim-based access control, so file servers retrieve user claims and domains providing claims have Windows Server 2012 domain controllers in all the file server sites 526
Configuring forest root DCs 526

Configuring domains which provides claims and compound authentication 527
Configuring file servers to request claims on the behalf of users 527
Configuration 3: Device-based access control needed, but cannot wait until all domain controllers can be upgraded 527
Considerations for using smartcards for Central Access Polices 527
Best Practices for Deploying Central Access Policies 528
Delegating of administration for Dynamic Access Control 528
Exception Mechanisms for Planning Central Access Policies 529
Tools for Deployment 530
Appendix: Deployment Configurations for Central Access Policies 531

Deploy a Central Access Policy (Demonstration Steps) 532
Set up a test environment 532
Plan: Identify the need for policy and the configuration required for deployment 533
Implement: Configure the components and policy 534
Deploy the central access policy 540
Maintain: Change and stage the policy 542
Next Steps 545

Deploy Claims Across Forests 545
Claim transformation rules 545
Linking claim transformation policies to forests 545
In this scenario 546
Roles and features included in this scenario 546

Deploy Claims Across Forests (Demonstration Steps) 547
Scenario overview 547
Set up the prerequisites and the test environment 547
Set up claims transformation on trusted forest (Adatum) 548
Create a claims transformation policy in Adatum 549
Set a claims transformation link on Adatum’s trust domain object 549
Set up claims transformation in the trusting forest (Contoso) 549
Create a claims transformation policy in Contoso 550
Set a claims transformation link on Contoso’s trust domain object 550
Validate the scenario 551
Additional scenarios for claims transformation policies 551
See also 552

Claims Transformation Rules Language 553
Tools for authoring claims transformation policies 553
Active Directory claims transformation rules language 554
Syntax overview 554
Runtime operation 554
Special rules semantics 556

Security considerations 556
Other language considerations 557
Sample transformation rules 558
Examples of rules parser errors 558
Language terminals 560
Language syntax 561

Scenario: File Access Auditing 563
In this scenario 564
Roles and features included in this scenario 565

Plan for File Access Auditing 565

Deploy Security Auditing with Central Audit Policies (Demonstration Steps) 567
Configure global object access policy 567
Update Group Policy settings 568
Verify that the global object access policy has been applied 569
See also 569

Scenario: Access-Denied Assistance 569
Scenario description 570
In this scenario 570
Practical applications 571
Features included in this scenario 571

Plan for Access-Denied Assistance 571
1.1 Determine the access-denied assistance model 572
1.2. Determine who should handle access requests 572
1.3. Customize the access-denied assistance message 572
1.4. Plan for exceptions 573
1.5. Determine how access-denied assistance is deployed 573
See also 573

Deploy Access-Denied Assistance (Demonstration Steps) 574
Step 1: Configure access-denied assistance 574
Step 2: Configure the email notification settings 578
Step 3: Verify that access-denied assistance is configured correctly 578
See also 579

Scenario: Classification-Based Encryption for Office Documents 579
Scenario description 579
In this scenario 580
Roles and features included in this scenario 580

Planning Considerations for Encryption of Office Documents 582
Determining files to automatically encrypt 582

Determining the rights policy template to use when encrypting files ... 584
Multi-machine considerations ... 585
Dynamic scope using the FolderUsage property ... 585
Setting management property values ... 586
Moving configurations between computers ... 586

Deploy Encryption of Office Files (Demonstration Steps) ... 587
Step 1: Enable resource properties ... 587
Step 2: Create classification rules ... 588
Step 3: Use file management tasks to automatically protect documents with AD RMS ... 591
Step 4: View the results ... 592
Step 5: Verify protection with AD RMS ... 593

Scenario: Get Insight into Your Data by Using Classification ... 593
Scenario description ... 593
In this scenario ... 594
Practical applications ... 594
Features included in this scenario ... 594

Plan for Automatic File Classification ... 594
1.1. Identify what information to classify in your environment ... 595
1.2. Identify how to classify files ... 595
1.3. Considerations for multiple computers ... 596
See also ... 596

Deploy Automatic File Classification (Demonstration Steps) ... 596
Step 1: Create resource property definitions ... 597
Step 2: Create a string content classification rule ... 597
Step 3: Create a regular expression content classification rule ... 599
Step 4: Verify that the files are classified correctly ... 600
See also ... 600

Set up Manual File Classification ... 600
Create Resource Properties ... 601
Set Group Policy Settings for Manual File Classification ... 601
Classify files and folders manually ... 602
Classification properties lists ... 602

Scenario: Implement Retention of Information on File Servers ... 603
Scenario description ... 603
In this scenario ... 603
Features included in this scenario ... 603

Plan for Retention of Information on File Servers ... 604
1.1. Determine the retention schedule ... 604

1.2. Identify files to be retained 605
1.3 Considerations for multiple computers 605
See also 605

Deploy Implementing Retention of Information on File Servers (Demonstration Steps) 605
Prerequisites 606
Step 1: Create resource property definitions 606
Step 2: Configure notifications 606
Step 3: Create a file management task 607
Step 4: Classify a file manually 609
See also 609

Appendix A: Dynamic Access Control Glossary 609
See Also 612

Appendix B: Setting Up the Test Environment 612
Prerequisites 612
Build the test lab virtual machines 613
Install the Hyper-V role 613
Create an internal virtual network 613
Build the domain controller 613
Build the file server and AD RMS server (FILE1) 616
Install File Services Resource Manager 616
Install the Microsoft Office Filter Packs on the file server 616
Configure email notifications on FILE1 617
Create groups on FILE1 617
Create files and folders on FILE1 617
Install Active Directory Rights Management Services 618
Build the mail server (SRV1) 623
Build the client virtual machine (CLIENT1) 623
Lab setup for deploying claims across forests scenario 624
Build a virtual machine for DC2 624
Set up a new forest called adatum.com 624
Set contoso.com as a trusting forest to adatum.com 625
Create additional users in the Adatum forest 626
Create the Company claim type on adataum.com 626
Enable the Company resource property on contoso.com 627
Enable Dynamic Access Control on adatum.com 627
Create the Company claim type on contoso.com 628
Create the central access rule 628
Create the central access policy 629
Publish the new policy through Group Policy 629
Create the Earnings folder on the file server 630
Set classification and apply the central access policy on the Earnings folder 630

Hosting-Friendly Web Server Platform (IIS): Scenario Overview 631
Scenario Description 631
Web Server Scenarios 631
Practical Applications 632
See Also 633

Build a Static Website on IIS 633
Prerequisites 634
Step 1: Install the IIS Web Server 634
Step 2: Add a Website 635
Step 3: Configure Anonymous Authentication 637
Step 4: Configure the Default Documents 638
Step 5: Configure Static Content Compression 638
Next Steps 639
See also 639

Configure Request Filtering in IIS 640
Prerequisites 640
General Request Filter Settings 640
File Name Extensions 642
Filtering Rules 643
Hidden Segments 644
URL Filtering 644
HTTP Verbs 645
Header Size Limits 646
Query Strings 646
Request Filter Logging 646
See Also 647

Configure Logging in IIS 647
Prerequisites 648
Configure Logging at the Site Level 648
Configure Per-site Logging at the Server Level 650
Configure Per-server Logging at the Server Level 650
Select W3C Fields to Log 650
Configure Log File Rollover Options 651
See Also 652

Build a Classic ASP Website on IIS 652
Prerequisites 653
Step 1: Install the IIS Web Server 653
Step 2: Add a Classic ASP Website 655
Step 3: Edit ASP Application Settings 656
Next Steps 663

See also 663

Build an ASP.NET Website on IIS 663
Scenario Description 663
In This Scenario 664
Practical Applications 664
Software Requirements 664
See Also 664

Plan an ASP.NET Website on IIS 665

Step 1: Plan IIS Web Server and ASP.NET Modules Installation 665
1.1. Plan to Install IIS and ASP.NET Modules 666
1.2. Plan to Add the ASP.NET Application 666
See Also 666

Step 2: Plan ASP.NET Settings 667
2.1. Session State Settings 667
Store session state in process 667
Store session state by using state server 668
Store session state by using SQL server 669
Cookie mode for session state 669
2.2. Pages and Controls Settings 671
2.3. Application Settings 671
2.4. .NET Compilation Settings 672
2.5. .NET Globalization Settings 672

Step 3: Plan Data Source Settings 673
3.1. Data source connection strings 673
3.2. ASP.NET providers 673
3.3. .NET profiles 674
3.4. .NET roles 675
3.5. .NET users 675

Step 4: Plan Application Security 675
4.1. Isolate Web Applications 676
4.2. .NET Trust Levels 676
4.3. .NET Authentication 677
ASP.NET Forms Authentication 677
Forms authentication basics 678
Authentication cookies 678
ASP.NET Impersonation Authentication 680
4.4. Machine Key Settings 681
4.5. TLS/SSL Communication 681
Server Certificates 682

SSL Binding 682
Require SSL for Your Site 683
Client Certificates 683

Configure an ASP.NET Website on IIS 683

Step 1: Install IIS and ASP.NET Modules 684
Installing IIS and ASP.NET Modules 684
Adding the ASP.NET Application 686
See Also 687

Step 2: Configure ASP.NET Settings 687
2.1. Session State Settings 688
Store Session State in Process 688
Store Session State by using State Server 689
Store Session State by using SQL Server 690
Cookie Mode for Session State 692
2.2. Pages and Controls Settings 694
Edit Pages and Controls 694
Add a Custom Control 694
2.3. Application Settings 695
2.4. .NET Compilation Settings 696
2.5. .NET Globalization Settings 698

Step 3: Configure Data Source Settings 700
3.1. Data Source Connection Strings 700
3.2. ASP.NET Providers 701
3.3. .NET Profiles 704
3.4. .NET Roles 706
3.5. .NET Users 707

Step 4: Configure Application Security 707
4.1. Isolate Web Applications 708
4.1. .NET Trust Levels 709
4.2. .NET Authentication 709
ASP.NET Forms Authentication 710
ASP.NET Impersonation Authentication 712
4.3. Machine Key Settings 714
4.4. TLS/SSL Communication 714
SSL Binding 714
Require SSL for Your Site 715
Client Certificates 716

Build an FTP Site on IIS 717
Prerequisites 717

Step 1: Install FTP on an Existing IIS Web Server 718
Step 2: Add an FTP Site 718
Step 3: Configure FTP Site Defaults 720
Step 4: Configure Firewall Support 721
Step 5: Configure User Isolation 722
Step 6: Configure Directory Browsing Options 723
Step 7: Configure Logon Attempt Restrictions 724
Step 8: Configure Request Filtering 724
Step 9: Configure FTP Logging 725
Step 10: Configure FTP Messages 725
See Also 726

Build a PHP Website on IIS 727
Scenario Description 727
In This Scenario 727
Practical Applications 727
Software Requirements 728
See Also 728

Plan a PHP Website on IIS 728

Step 1: Plan IIS Web Server and PHP Installation 729
1.1. Plan to Install IIS 729
1.2. Plan to Download and Install PHP 729
1.3. Plan to Add a PHP Application 730
See Also 730

Step 2: Plan PHP Settings 730
2.1. Plan WinCache Configuration 731
2.2. Plan Other PHP Settings 731
Required Settings 731
Optional Settings 732
2.3 Plan PHP Extensions 733
See Also 734

Step 3: Plan PHP Application Security 734
3.1. PHP Configuration Settings for Security 734
Disable File Handling for Remote URLs 734
Disable Register_Globals 735
Restrict File System Read/Write 735
Disable Safe Mode 735
Limit Script Execution Time 735
Limit Memory Usage and File Size 735
Configure Error Logging 736
Enable FastCGI Impersonation 736

Disable FastCGI Logging ... 736
Hide PHP Presence ... 736
3.2. Web Server and PHP Application Security ... 736
Isolate Web Applications ... 736
Enable Per-site PHP Configuration ... 737
Use Request Filtering ... 737
See Also ... 737

Configure a PHP Website on IIS ... 737

Step 1: Install IIS and PHP ... 738
1.1. Install IIS ... 738
1.2 Install PHP by using Web PI ... 739
1.3. Download and Install PHP Manually ... 740
1.4. Add Your PHP Application ... 741
See Also ... 742

Step 2: Configure PHP Settings ... 742
2.1. Configure WinCache ... 743
2.2. Configure Other PHP Settings ... 743
2.3 Configure PHP Extensions ... 744
See Also ... 744

Step 3: Configure PHP Application Security ... 744
3.1. Configure PHP Settings for Security ... 744
3.2. Configure Web Server and PHP Application Security ... 745
Isolate Web Applications ... 745
Enable Per-site PHP Configuration ... 746
Per-site PHP Process Pools ... 746
Specifying Php.ini Location ... 747
Use Request Filtering ... 748
See Also ... 748

Build a Web Farm with IIS Servers ... 749
Scenario Description ... 749
In This Scenario ... 749
Practical Applications ... 750
Software Requirements ... 750

Plan a Web Farm with IIS Servers ... 750

Step 1: Plan IIS Web Farm Infrastructure ... 751
1.1. Decide on Web Farm Infrastructure ... 751
Local Content Infrastructure ... 751

Shared Network Content Infrastructure 752
The Infrastructure Chosen for This Scenario 752
1.2. Use ARR for Load Balancing 753
1.3. Start with a Functional Website 753
See Also 753

Step 2: Plan IIS Web Farm Configuration 753
2.1. Plan for Shared Content 754
2.2. Plan for Shared Configuration 754
2.3 Plan to Add Web Servers 754
See Also 754

Step 3: Plan IIS Web Farm Load Balancing 755
3.1. Plan Load Balancing with ARR 755
3.2. Survey Other Features of ARR 755
See Also 757

Step 4: Plan SSL Central Certificate Store 758
4.1. Introduction to Centralized Certificates 758
4.2 Plan a Central Certificate Store 758
See Also 758

Step 5: Plan Application Deployment 759
5.1. Deploy Websites with FTP 759
5.2 Deploy Web Applications with Web Deploy 759
See Also 760

Configure a Web Farm with IIS Servers 760

Step 1: Install IIS Web Farm Infrastructure 760
1.1. Install IIS with Appropriate Modules 761
1.2 Install ARR for Load Balancing 762
1.3 Set up Your Website on One Web Server 763
See Also 763

Step 2: Configure IIS Web Farm Servers 763
2.1. Prepare Your Back-end File Server 763
2.2. Configure Shared Content 764
2.3. Set up Shared Configuration 765
2.4. Add Web Servers to Your Farm 765
See Also 766

Step 3: Configure IIS Web Farm Load Balancing 766
3.1. Create a Server Farm with ARR 767
3.2. Configure Load Balancing with ARR 767
3.3. Change Application Pool Settings 767

See Also 768

Step 4: Configure SSL Central Certificate Store 768
4.1. Configure a Central Certificate Store 768
See Also 769

Step 5: Configure Application Deployment 769
5.1. Install and Configure FTP for Your Web Farm 769
5.2. Install and Test Web Deploy for Your Web Farm 771
5.3. Where do I go from here? 772

Deploying Fast and Efficient File Servers for Server Applications 775
Overview 775
Requirements and recommendations 775
SMB Direct 775
SMB Multichannel 776
Install the required roles, role services, and features 776
Step-by-step instructions 776
Step 1: Verify the basic network configuration 777
Step 2: Configure a failover cluster 777
Step 3: Configure the networks for the failover cluster 777
Step 4: Configure a Scale-out File Server 778
Step 5: Verify each file server name has two addresses 778
Step 6: Configure a Hyper-V or Microsoft SQL Server client 779
Step 7: Verify servers are using SMB Multichannel and SMB Direct 779
Step 8: Monitor file shares using Performance Counters 779

Prepare to Migrate iSCSI Software Target 1089
Prepare the destination server 1089
Back up the source server 1089
Prepare the source server 1089
Cluster resource group configuration 1089
iSCSI Target portal configuration 1091
iSNS configuration 1092
CHAP and Reverse CHAP configuration 1092
Snapshot storage configuration 1092
Disconnect the iSCSI initiators 1092
Capture the existing settings: stand-alone configuration 1093
Capture the existing settings: clustered configuration 1093
Remove the network identity of the iSCSI Software Target computer 1094
Prepare the iSCSI initiator computers 1095
Capture the session information 1095
Disconnect the session 1095
See Also 1095

Migrate iSCSI Software Target 1096
Migrating iSCSI Software Target in a standalone configuration 1096
Establish network identity of the iSCSI Target Server computer 1096
Configure the iSCSI Target Server portal 1096
Configure iSNS settings 1097

Configure storage ... 1097
Configure the Volume Shadow Copy Service ... 1097
Transfer the virtual disk ... 1098
Import the iSCSI Software Target settings in a stand-alone configuration ... 1098
Configure shadow storage for the virtual disks ... 1099
Configure CHAP and Reverse CHAP ... 1099
Migrating iSCSI Software Target in a failover cluster ... 1099
Migrate resource groups ... 1100
Import the iSCSI Software Target settings in a failover cluster ... 1100
Migrate iSCSI Target Server Providers ... 1101
See Also ... 1101

Verify the iSCSI Software Target Migration ... 1102
Verifying the destination server configuration ... 1102
Verify the listening endpoints ... 1102
Verify the basic connectivity ... 1102
Perform a Best Practices Analyzer scan ... 1103
Verifying the configuration of iSCSI initiator computers ... 1103
Verify that the iSCSI initiators can discover iSCSI Target Server ... 1103
Verify that the iSCSI initiators can log on ... 1103
See Also ... 1104

Troubleshoot the iSCSI Software Target Migration ... 1104

Migrate Windows Server Update Services to Windows Server 2012 ... 1490

Step 1: Plan for WSUS Migration ... 1491
1.1. Know supported operating systems ... 1491
1.2. Review supported migration scenarios ... 1491
1.3. Review migration scenarios that are not supported ... 1492
See also ... 1492

Step 2: Prepare to Migrate WSUS ... 1492
2.1. Prepare before you start the migration ... 1493
2.2. Prepare the destination server ... 1494
2.3. Prepare the source server ... 1494

See also ... 1494

Step 3: Migrate WSUS ... 1495
3.1. Migrate WSUS update binaries ... 1495
3.2. Migrate WSUS security groups ... 1496
3.3. Back up the WSUS database ... 1497
3.4. Change the WSUS server identity ... 1501
3.5. Apply security settings ... 1501
Point the downstream servers to the new WSUS server ... 1502
Point the WSUS clients to the new WSUS server ... 1502
3.6. Review additional considerations ... 1503
See also ... 1503

Step 4: Verify the WSUS Migration ... 1504
4.1. Verify the destination server configuration ... 1504
4.2. Verify client computer functionality ... 1504
See also ... 1504

Best Practices Analyzer for Remote Access: Configuration (Section 1) 1626
Best Practices Analyzer and configuration rules 1626
Topics in this section 1626

RRAS: The inbound Certification Authority (CA) should be configured 1627
Issue 1627
Impact 1627
Resolution 1627

RRAS: At least one valid IKEv2 certificate should be present on the RRAS server 1628
Issue 1628
Impact 1628
Resolution 1628

RRAS: A valid CA certificate for the Remote Access Server certificate must be present in the TRCA certificate store 1629
Issue 1629
Impact 1629
Resolution 1630

RRAS: A valid CA certificate for the Site-to-Site VPN interface certificate must be present in the TRCA certificate store 1630
Issue 1630
Impact 1630
Resolution 1631

RRAS: The server certificate expires within 7 days 1631
Issue 1631
Impact 1631
Resolution 1631

RRAS: The CA certificate of the Remote Access Server certificate in the TRCA certificate store expires within 7 days 1632
Issue 1632
Impact 1633
Resolution 1633

RRAS: The certificate for the Site-to-Site VPN interface expires within 7 days 1633
Issue 1633
Impact 1634
Resolution 1634

RRAS: The CA certificate for the Site-to-Site VPN interface certificate expires within 7 days . 1634
Issue 1634
Impact 1635
Resolution 1635

RRAS: The CA certificate for the destination server of Site-to-Site VPN interface expires within 7 days 1635
Issue 1635

Impact 1636
Resolution 1636

RRAS: The Remote Access server certificate must have a public IP address for Alternate Subject Name 1636
Issue 1637
Impact 1637
Resolution 1637

RRAS: The Site-to-Site VPN interface name must match the Username 1637
Issue 1638
Impact 1638
Resolution 1638

RRAS: No two Site-to-Site VPN interfaces with PSK based authentication should have the same destination 1639
Issue 1639
Impact 1639
Resolution 1639

RRAS: For PSK authentication, the destination cannot be configured as a Fully Qualified Domain Name (FQDN) 1640
Issue 1641
Impact 1641
Resolution 1641

RRAS: The Site-to-Site VPN interface should be configured with a Source IP address 1641
Issue 1642
Impact 1642
Resolution 1642

RRAS: Custom policies configured for the Site-to-Site VPN interface should be a subset of Remote Access server global policies 1642
Issue 1643
Impact 1643
Resolution 1643

Best Practices Analyzer for Remote Access: Configuration (Section 2) 1643
Best Practices Analyzer and configuration rules 1643
Topics in this section 1644

RRAS: The number of ports available for the Routing Domain should not be less than the number of VPN and Site-to-Site VPN interfaces 1644
Issue 1645
Impact 1645
Resolution 1645

RRAS: A static pool should be configured for IPv4 address assignment to the VPN client 1645
Issue 1646
Impact 1646
Resolution 1646

RRAS: The static pool IPv4 addresses must be valid unicast IPv4 addresses 1647
Issue 1647
Impact 1647
Resolution 1647

RRAS: The VPN Tenant Name must be specified 1648
Issue 1648
Impact 1648
Resolution 1648

RRAS: The VPN Tenant Name for a Routing Domain must not be a subset of another Routing Domain's Tenant Name 1649
Issue 1649
Impact 1649
Resolution 1649

RRAS: The default route (IPv4 or IPv6) should not be advertised to the peers 1650
Issue 1650
Impact 1650
Resolution 1650

RRAS: The default route (IPv4 or IPv6) should not be accepted from the peers 1651
Issue 1651
Impact 1651
Resolution 1651

RRAS: The BGP peer IP address should not be assigned to a local network interface 1652
Issue 1652
Impact 1652
Resolution 1652

RRAS: A local global IPv6 address must be configured on the BGP Router 1653
Issue 1653
Impact 1653
Resolution 1653

RRAS: Multiple routes with different Next-Hop values and the same Destination prefix are configured 1654
Issue 1654
Impact 1654
Resolution 1654

RRAS: The BGP peer's Hold-Timer should not be set to the value 0 1655
Issue 1655
Impact 1655
Resolution 1655

RRAS: BGP peer's Hold-Timer should not be set to a very low value 1656
Issue 1656
Impact 1656
Resolution 1656

RRAS: All the ingress route advertisements should not be dropped because of a routing policy 1657
Issue 1657
Impact 1657
Resolution 1657

RRAS: All the egress route advertisements should not be dropped because of a routing policy 1658
Issue 1658
Impact 1658
Resolution 1658

RRAS: BGP peers should not be configured for manual (passive) peering mode 1659
Issue 1659
Impact 1659
Resolution 1659

Best Practices Analyzer for Remote Access: Configuration (Section 3) 1660
Best Practices Analyzer and configuration rules 1660
Topics in this section 1660

RRAS: For BGP Peering over IPv6 addresses, IPv4 routes should not be configured for advertisement 1661
Issue 1661
Impact 1661
Resolution 1661

RRAS: IdleHoldTimer should not be set to a high value (> 10 sec) 1662
Issue 1662
Impact 1663
Resolution 1663

RRAS: Max Prefix policy should be configured for all BGP Peers 1663
Issue 1663
Impact 1663
Resolution 1664

RRAS: The total number of prefixes learned is in proximity of the Maximum Allowed Prefixes 1664
Issue 1664
Impact 1664
Resolution 1665

RRAS: A triggering route must be configured on the Site-to-Site VPN interface for the BGP peers 1665
Issue 1665
Impact 1666
Resolution 1666

RRAS: The Site-to-Site VPN triggering route should be a specific address (/32 for IPv4 address, /128 for IPv6 address) 1666
Issue 1667
Impact 1667
Resolution 1667

RRAS: The Site-to-Site VPN interface's traffic filters should not be blocking BGP traffic 1668
Issue 1668
Impact 1668
Resolution 1668

RRAS: The Site-to-Site VPN interface's traffic filters should not be blocking VSID interface traffic 1669
Issue 1669
Impact 1670
Resolution 1670

RRAS: The Site-to-Site VPN interface's traffic filters should not be blocking VPN client traffic 1670
Issue 1671
Impact 1671
Resolution 1671

RRAS: The VPN static address pool should be configured as custom networks on the BGP router 1672
Issue 1672
Impact 1672
Resolution 1672

Best Practices Analyzer for Remote Access: Performance and Operation 1673
Best Practices Analyzer performance and operation rules 1673
Topics in this section 1673

RRAS: Rate-limiting (Tx/Rx BandwidthKbps) should be set to a value as per the network requirements 1673
Issue 1674

Impact ... 1674
Resolution ... 1674

RRAS: Rate-limiting parameters (Tx/Rx BandwidthKbps) should not have a significant difference in the values ... 1674
Issue ... 1675
Impact ... 1675
Resolution ... 1675

RRAS: The CapacityKbps parameter should be configured with a value as per the network requirements ... 1676
Issue ... 1676
Impact ... 1676
Resolution ... 1676

RRAS: The routes being advertised to the peers must be locally resolvable ... 1677
Issue ... 1677
Impact ... 1677
Resolution ... 1677

Work Folders Best Practices Analyzer ... 1678

The Windows Sync Share service should be set to start automatically ... 1678
Issue ... 1678
Impact ... 1678
Resolution ... 1678
See also ... 1679

Work Folders should be installed on all nodes of the failover cluster ... 1679
Issue ... 1679
Impact ... 1679
Resolution ... 1679
See also ... 1680

All nodes in a failover cluster should be reachable to Work Folders ... 1680
Issue ... 1680
Impact ... 1680
Resolution ... 1680
See also ... 1681

The Work Folders server should be domain joined ... 1681
Issue ... 1681
Impact ... 1681
Resolution ... 1681
See also ... 1682

The sync share should be located in a valid folder 1682
Issue 1682
Impact 1682
Resolution 1682
See also 1682

A current SSL certificate should be configured for this Work Folders server 1683
Issue 1683
Impact 1683
Resolution 1683
See also 1683

Windows Firewall should open port 80 and 443 for Work Folders 1683
Issue 1684
Impact 1684
Resolution 1684
See also 1684

A staging area should exist for the sync share 1684
Issue 1685
Impact 1685
Resolution 1685

Best Practices Analyzer for Web Application Proxy 1685
More information about Web Application Proxy 1686
Topics in this section 1686

Web Application Proxy must be configured before it is used 1686
Issue 1687
Impact 1687
Resolution 1687

Web Application Proxy: The external and backend server URLs are different and URL translation is disabled 1688
Issue 1688
Impact 1688
Resolution 1688

Web Application Proxy: The service is not configured to run automatically 1690
Issue 1691
Impact 1691
Resolution 1691

Web Application Proxy: The AD FS Proxy service is not configured to run automatically 1691
Issue 1692

Impact 1692
Resolution 1692

Web Application Proxy: This server is not included in the ConnectedServersName list 1693
Issue 1693
Impact 1693
Resolution 1693

Web Application Proxy: The ConfigurationChangesPollingIntervalSec value is high 1694
Issue 1694
Impact 1694
Resolution 1694

Web Application Proxy: Application is using an external certificate that is not yet valid 1695
Issue 1696
Impact 1696
Resolution 1696

Web Application Proxy: Application is using an external certificate that is about to expire 1698
Issue 1698
Impact 1699
Resolution 1699

Web Application Proxy: Application is using an external certificate that has no private key 1701
Issue 1701
Impact 1701
Resolution 1702

Web Application Proxy: Application is using an external certificate that has expired 1704
Issue 1704
Impact 1704
Resolution 1704

Web Application Proxy: Application is configured to use an external certificate that is not present on this server 1707
Issue 1707
Impact 1707
Resolution 1707

Web Application Proxy: Some applications are configured to perform backend authentication using Integrated Windows authentication but the server is not joined to a domain 1708
Issue 1709
Impact 1709
Resolution 1709

Web Application Proxy: A cluster of Web Application Proxy servers is deployed and DirectAccess is also installed 1710
Issue 1711
Impact 1711
Resolution 1711

Server Roles and Technologies in Windows Server 2012 R2 and Windows Server 2012 1712

Active Directory 1715

What's New in Active Directory in Windows Server 2012 R2 1715

Active Directory Certificate Services Overview 1716
Role description 1717
Practical applications 1717

Dynamic Access Control: Scenario Overview 2478
In this scenario 2478
Dynamic Access Control Content Roadmap 2478
See also 2487

Scenario: Central Access Policy 2487
In this scenario 2490
Roles and features included in this scenario 2490

Plan for a Central Access Policy Deployment 2491
Process to map a business request to a central access policy 2492
Understand and translate business intent 2492
Express access policy in Windows Server 2012 constructs 2492
Determine the user groups, resource properties and claim types 2492
Determine the servers where this policy should be applied to 2493
Planning Guidelines for Deploying Central Access Policies 2493
Using Security Groups for Dynamic Access Control 2493
Using security groups to limit access to data 2493
Using conditional expressions to reduce complexity of security groups 2494
Using User Claims 2494
Operations to enable user claims 2495
Enable the domain controllers to provide claims and compound authentication on request 2495
Considerations for using user claims in the file server discretionary ACLs without using Central Access Policies 2496
Using Device Claims and Device Security Groups 2496
Considerations for using static device claims 2496
Operations to enable device claims 2496
Enable the Windows 8 devices in domain to request claims and compound authentication 2496
Enable the Windows 8 devices to request claims and compound authentication using custom policy 2497
Enable the Windows 8 device to receive compound authentication 2497
Configuring central access policies with different options 2498
Configuration 1: Domains providing claims and compound authentication have all Windows Server 2012 DCs 2498
Configuring forest root DCs 2498
Configuring domains which provide claims and compound authentication 2498
Configuring devices to request claims and compound authentication 2499
Configuring resources to receive compound authentication 2499
Configuration 2: Only user claim-based access control, so file servers retrieve user claims and domains providing claims have Windows Server 2012 domain controllers in all the file server sites 2499
Configuring forest root DCs 2499
Configuring domains which provides claims and compound authentication 2500
Configuring file servers to request claims on the behalf of users 2500
Configuration 3: Device-based access control needed, but cannot wait until all domain controllers can be upgraded 2500
Considerations for using smartcards for Central Access Polices 2500
Best Practices for Deploying Central Access Policies 2501
Delegating of administration for Dynamic Access Control 2501
Exception Mechanisms for Planning Central Access Policies 2502

Tools for Deployment 2503
Appendix: Deployment Configurations for Central Access Policies 2504

Deploy a Central Access Policy (Demonstration Steps) 2505
Set up a test environment 2505
Plan: Identify the need for policy and the configuration required for deployment 2506
Implement: Configure the components and policy 2507
Deploy the central access policy 2513
Maintain: Change and stage the policy 2515
Next Steps 2518

Scenario: File Access Auditing 2518
In this scenario 2519
Roles and features included in this scenario 2520

Plan for File Access Auditing 2520

Deploy Security Auditing with Central Audit Policies (Demonstration Steps) 2522
Configure global object access policy 2523
Update Group Policy settings 2523
Verify that the global object access policy has been applied 2524
See also 2524

Scenario: Access-Denied Assistance 2524
Scenario description 2525
In this scenario 2525
Practical applications 2526
Features included in this scenario 2526

Deploy Access-Denied Assistance (Demonstration Steps) 2526
Step 1: Configure access-denied assistance 2526
Step 2: Configure the email notification settings 2530
Step 3: Verify that access-denied assistance is configured correctly 2531
See also 2531

Scenario: Classification-Based Encryption for Office Documents 2531
Scenario description 2531
In this scenario 2532
Roles and features included in this scenario 2532

Deploy Encryption of Office Files (Demonstration Steps) 2534
Step 1: Enable resource properties 2535
Step 2: Create classification rules 2535
Step 3: Use file management tasks to automatically protect documents with AD RMS 2538
Step 4: View the results 2539
Step 5: Verify protection with AD RMS 2540

Scenario: Get Insight into Your Data by Using Classification 2540
Scenario description 2540
In this scenario 2541
Practical applications 2541
Features included in this scenario 2541

Deploy Automatic File Classification (Demonstration Steps) 2542
Step 1: Create resource property definitions 2542
Step 2: Create a string content classification rule 2543
Step 3: Create a regular expression content classification rule 2544
Step 4: Verify that the files are classified correctly 2545
See also 2546

Scenario: Implement Retention of Information on File Servers 2546
Scenario description 2546
In this scenario 2546
Features included in this scenario 2547

Deploy Implementing Retention of Information on File Servers (Demonstration Steps) 2547
Prerequisites 2547
Step 1: Create resource property definitions 2548
Step 2: Configure notifications 2548
Step 3: Create a file management task 2549
Step 4: Classify a file manually 2550

Appendix A: Dynamic Access Control Glossary 2569
See Also 2571

Appendix B: Setting Up the Test Environment 2571
Prerequisites 2572
Build the test lab virtual machines 2572
Install the Hyper-V role 2572
Create an internal virtual network 2573
Build the domain controller 2573
Build the file server and AD RMS server (FILE1) 2575
Install File Services Resource Manager 2576
Install the Microsoft Office Filter Packs on the file server 2576
Configure email notifications on FILE1 2576
Create groups on FILE1 2577
Create files and folders on FILE1 2577
Install Active Directory Rights Management Services 2578
Build the mail server (SRV1) 2582
Build the client virtual machine (CLIENT1) 2582
Lab setup for deploying claims across forests scenario 2583
Build a virtual machine for DC2 2583
Set up a new forest called adatum.com 2584
Set contoso.com as a trusting forest to adatum.com 2585
Create additional users in the Adatum forest 2585
Create the Company claim type on adataum.com 2586
Enable the Company resource property on contoso.com 2587
Enable Dynamic Access Control on adatum.com 2587
Create the Company claim type on contoso.com 2587
Create the central access rule 2588
Create the central access policy 2588
Publish the new policy through Group Policy 2589
Create the Earnings folder on the file server 2590

Set classification and apply the central access policy on the Earnings folder 2590

Cluster-Aware Updating: Frequently Asked Questions ... 3557
What is CAU? ... 3558
Does CAU work with Windows Server 2008 R2 or Windows 7? ... 3558
Is CAU functionality limited to only specific clustered applications? ... 3558
Does CAU support updates from Microsoft Update and Windows Update? ... 3558
Does CAU support WSUS updates? ... 3558
Can CAU apply limited distribution release updates? ... 3558
Can I use CAU to apply cumulative updates? ... 3559
Can I schedule CAU to apply updates? ... 3559
Can CAU updates be scheduled when a backup is in progress? ... 3559
Can CAU work well with System Center Configuration Manager? ... 3559
Do I need administrative credentials to run CAU? ... 3560
Can I script CAU functionality to automate it further? ... 3560
When CAU coordinates updates, what happens to the clustered roles that are active on each cluster node? ... 3560
How does CAU select the target nodes that each clustered role should fail over to? ... 3560
Does CAU load balance the clustered roles at the end of the updating process? ... 3560
How does CAU select the order of nodes to update? ... 3561
When a CAU Updating Run is initiated on the cluster, what happens if all the cluster nodes are not online? ... 3561
Can I use CAU to select and update only a single node? ... 3561
Can CAU report cluster node updates that are initiated from outside CAU? ... 3561
Is CAU flexible enough to support my unique IT process needs? ... 3561
How can I export the CAU preview and update results? ... 3562
How do I install CAU? ... 3562

Does CAU need any service or component running on the cluster nodes that are being updated? 3563
What is the difference between using CAU and using System Center 2012 Virtual Machine Manager to update Hyper-V clusters? 3563
Can I use remote-updating on a cluster that is configured for self-updating? 3563
Can I reuse my cluster update settings across clusters? 3563
Where can I get more information about the public CAU plug-in specification? 3563
See also 3564

Requirements and Best Practices for Cluster-Aware Updating 3564
Install the Failover Clustering feature and the Failover Clustering Tools 3564
Obtain an administrator account 3565
Verify the cluster configuration 3565
Configure the nodes for remote management 3566
Enable Windows Management Instrumentation 3567
Enable Windows PowerShell and Windows PowerShell remoting 3567
Install .NET Framework 4.5 3568
Enable a firewall rule to allow automatic restarts 3568
Best practices recommendations for using CAU 3568
Recommendations for applying Microsoft updates 3568
Apply Microsoft updates in branch office scenarios 3569
Recommendations for using the Microsoft.HotfixPlugin 3570
Additional recommendations 3570
Test cluster updating readiness 3571
Tests for cluster updating readiness 3571

What's New in Data Deduplication in Windows Server 2012 R2 3617
Feature description 3617
New and changed functionality 3617
Data deduplication for remote storage of VDIworkloads 3618
Expand an optimized file on its original path 3619
See also 3619

Plan to Deploy Data Deduplication 3620
Step 1: Target deployments 3620
Step 2: Determine which volumes are candidates for deduplication 3620
Server and volume requirements for deduplication 3622
Unsupported configurations 3623

Deduplication considerations 3624
Step 3: Evaluate savings with the Deduplication Evaluation Tool 3625
Determine potential space reclamation with the Measure-DedupFileMetadata cmdlet..... 3626
Step 4: Plan the rollout, scalability, and deduplication policies..... 3627

Backup and Restore Considerations for Deduplicated Volumes 3628
Windows Server Backup 3628
Optimized backup considerations 3629
Incremental optimized backup considerations 3629
Full volume restore from optimized backup 3629
Selective restore from an optimized backup 3630
Selective partial volume restore to a newly formatted volume 3630
Selective restore from a backup store that allows data deduplication..... 3630
Non-optimized backup and restore 3631
Incremental non-optimized backup 3631

Data Deduplication Interoperability..... 3631
BranchCache..... 3632
Failover clusters 3632
DFS Replication 3632
File Server Resource Manager quotas 3632
Single Instance Storage 3633
Migrating SIS volumes..... 3633

Install and Configure Data Deduplication 3634
Prerequisites 3634
Step 1: Set up the server 3634
Step 2: Enable data deduplication 3635
Step 3: Set data deduplication jobs..... 3636
Optimization jobs 3636
Data Scrubbing jobs 3639
Garbage Collection jobs 3640
Step 4: Set data deduplication schedules 3640

Monitor and Report for Data Deduplication 3644
How do I tell if deduplication is keeping up with the rate of incoming data?..... 3648

Generation 2 FAQ ... 4214
Can I run generation 1 and generation 2 virtual machines together? ... 4214
Is there a performance gain to generation 2 virtual machines? ... 4214

What are the benefits of using a generation 2 virtual machine? 4214
How can I enable kernel debugging by using a COM port on a generation 2 virtual machine? 4214
Is RemoteFX supported by generation 2 virtual machines? 4215
Can I attach a physical CD or DVD to a generation 2 virtual machine? 4215
Can I attach a virtual hard disk in VHD format to a generation 2 virtual machine? 4215
Can a VHDX file that was converted from a VHD file be used to boot a generation 2 virtual machine? 4215
Can I resize a VHDX file that contains the boot volume for a generation 2 virtual machine while the virtual machine is running? 4215
What is the maximum size of a VHDX file that is supported by a generation 2 virtual machine? 4215
Can I create a VHDX file that can be used to boot both generation 1 and generation 2 virtual machines? 4215
Can I mount a VHDX file that is used by a generation 2 virtual machine? 4216
Can I tell whether a VHDX file was created by a generation 1 or a generation 2 virtual machine? 4216
Can a generation 2 VHDX file be attached to a generation 1 virtual machine? 4216
Can I import a generation 2 virtual machine to Hyper-V in Windows Server 2012? 4216
Is Secure Boot or UEFI firmware required on the physical host? 4216
Does the UEFI firmware in a generation 2 virtual machine support setup mode for Secure Boot? 4216
Can I run a UEFI shell or other UEFI application in a generation 2 virtual machine? 4216
Where are the boot entries for generation 2 virtual machines stored? 4217
What is the default generation of a new virtual machine? 4217
Can I change the generation of a virtual machine after it has been created? 4217
Why are 64-bit versions of Windows Server 2008 R2 and Windows 7 not supported as a guest operating system for generation 2 virtual machines? 4217
Why are 32-bit versions of Windows 8.1 and Windows 8 not supported as guest operation systems for generation 2 virtual machines? 4217
What is the maximum number of network adapters that can be supported by a generation 2 virtual machine? 4217
What is the maximum number of storage devices (VHDX files or DVD drives), that can be supported by generation 2 virtual machines? 4217
When I create a new virtual machine with the New-VM Windows PowerShell cmdlet, why does the generation 2 virtual machine not have a DVD drive? 4218
Does a generation 2 virtual machine support iSCSI or Fibre Channel boot? 4218
Can I perform a network installation that uses IPv6? 4218
Can I use a virtual floppy disk (.vfd) as an answer file for an unattended installation of a generation 2 virtual machine? 4218

Demonstrate Planned Failover in Hyper-V Replica ... 4258
Prerequisites ... 4259

Step 1: Enable the Hyper-V Role and create a virtual machine 4259
Step 2: Configure the Replica server to accept replication 4259
Step 3: Enable and begin replication of virtual machines 4261
Step 4: Monitor replication 4263
Step 5: Demonstrate test failover 4263
Step 6: Demonstrate planned failover 4264
See also 4265

Deploy Hyper-V Replica 4265

Step 1: Prepare to Deploy Hyper-V Replica 4265
1.1. Make basic planning decisions 4266
1.2. Install the Hyper-V server role 4268
1.3. Configure the firewall 4268
1.4. Configure Hyper-V Replica Broker 4269
1.5. Provide a certificate for encrypted data 4270
See also 4271

Step 2: Enable Replication 4271
2.1 Configure the Replica server 4272
2.2. Configure a Replica server that is part of a failover cluster (optional) 4273
2.3 Enable replication for virtual machines 4274
2.4 Configure primary server to receive replication 4276
See also 4276

Step 3: Test the Replication Deployment 4276
3.1. Perform test failover 4277
See also 4278

Step 4: Perform a Planned Failover 4278
4.1. Perform a planned failover 4278
See also 4279

Step 5: Respond to an Unplanned Failover 4280
5.1. Start the Replica virtual machines 4280
5.2. Start reverse replication 4281
See also 4282

Step 6: Configure and Use Extended Replication 4282
Enable extended replication 4283
Monitor extended replication 4284
Pause and resume extended replication 4284
Resynchronization 4285
Test failover with an extended Replica server 4286
New options for planned failover 4286

Unplanned failover from primary to Replica with an extended Replica server 4288
Unplanned failover when both primary and Replica servers go offline 4289
Moving primary or Replica virtual machines to different servers or clusters 4291
Removing replication or extended replication 4291

Hyper-V Configuration 4292

Configure Live Migration and Migrating Virtual Machines without Failover Clustering 4293
Prerequisites 4293
Step 1: [Optional] Configure constrained delegation 4295
Step 2: Configure the source and destination computers for live migration 4297
Step3: [optional] Configure performance options for live migration 4298
Step 4: Move a running virtual machine 4299
Step 5: [Optional] Move a running virtual machine again (back to the original host or to another host) 4299
See also 4300

Deploying optional features for network access authentication and Web services 4362
Deploying NPS1 4363
Planning the deployment of NPS1 4364
Install Network Policy Server (NPS) 4364
Register the NPS Server in the Default Domain 4365
Deploying WEB1 4366
Install the Web Server (IIS) server role 4366
Additional Technical Resources 4367
Appendices A through E 4368
Appendix A - Renaming computers 4368
Windows Server 2008 R2 and Windows 7 4368
Windows Server 2008 and Windows Vista 4369
Windows Server 2003 and Windows XP 4369
Appendix B - Configuring static IP addresses 4369
Windows Server 2008 R2 4370
Windows Server 2008 4370
Windows Server 2003 4371
Appendix C – Joining computers to the domain 4372
Windows Server 2008 R2 and Windows 7 4372
Windows Server 2008 and Windows Vista 4373
Windows Server 2003 and Windows XP 4373
Appendix D – Log on to the domain 4374
Windows Server 2008 R2 and Windows 7 4374
Windows Server 2008 and Windows Vista 4374
Windows Server 2003 and Windows XP 4375
Appendix E - Core Network Planning Preparation Sheet 4375
Installing Active Directory Domain Services and DNS 4376
Pre-installation configuration items for AD DS and DNS 4376
AD DS and DNS installation configuration items 4376
Configuring a DNS Reverse Lookup Zone 4377
Installing DHCP 4377

Pre-installation configuration items for DHCP 4378
DHCP installation configuration items 4378
Creating an exclusion range in DHCP 4379
Creating a new DHCP scope 4379
Installing Network Policy Server (optional) 4380
Pre-installation configuration items 4380
Network Policy Server installation configuration items 4380

Core Network Companion Guide: Server Certificate Deployment 4381
Prerequisites for using this guide 4381
About this guide 4382
Requirements for deploying server certificates 4382
What this guide does not provide 4383
Technology overviews 4383
EAP 4383
EAP in Windows Server 2012 4384
PEAP 4384
Features of PEAP 4385
Active Directory Certificate Services 4385

Server Certificate Deployment Overview 4385
Server certificate deployment components 4386
CA1 running the AD CS server role 4386
CAPolicy.inf 4387
Copy of the RAS and IAS servers certificate template 4387
Additional CA1 configuration 4387
WEB1 running the Web Services (IIS) server role 4387
Virtual directory for the CRL and AIA 4387
DC1 running the AD DS and DNS server roles 4388
Group Policy default domain policy 4388
DNS alias (CNAME) resource record 4388
NPS1 running the Network Policy Server role service of the Network Policy and Access Services server role 4388
Group Policy applied and certificate enrolled to NPS1 4388
Server certificate deployment process overview 4388

Server Certificate Deployment Planning 4389
Plan basic server configuration 4390
Plan domain access 4390
Plan the location and name of the virtual directory on your Web server 4390
Plan a DNS alias (CNAME) record for your Web server 4390
Plan configuration of CAPolicy.inf 4391
Plan configuration of the CDP and AIA extensions on CA1 4392
Plan the copy operation between the CA and the Web server 4393

Plan the configuration of the server certificate template on the CA 4393
Server Certificate Deployment 4393
Create an Alias (CNAME) Record in DNS for WEB1 4394
Configure WEB1 to Distribute Certificate Revocation Lists (CRLs) 4395
Prepare the CAPolicy.inf File 4396
Install the Certification Authority 4398
Configure the CDP and AIA Extensions on CA1 4400
Copy the CA Certificate and CRL to the Virtual Directory 4402
Configure the Server Certificate Template 4403
Configure Server Certificate Autoenrollment 4404
Refresh Group Policy 4405
Verify NPS Server Enrollment of a Server Certificate 4405
Additional Resources 4407
Core Network Companion Guide: Deploying Password-based 802.1X Authenticated Wireless Access 4408
About this guide 4408
Requirements 4409
What this guide does not provide 4410
Technology overviews 4411
IEEE 802.1X 4411
802.1X-capable wireless access points (APs) 4411
Wireless clients 4412
Support for IEEE 802.11 Standards 4412
Wireless network security methods 4413
Wireless authentication 4413
Wireless security encryption 4414
Enhanced encryption 4415
Wireless authentication and encryption pairs 4415
Active Directory Doman Services (AD DS) 4416
Active Directory Users and Computers 4416
Group Policy Management 4416
Server certificates 4417
EAP, PEAP, and PEAP-MS-CHAP v2 4417
Network Policy Server 4418
Bootstrap profiles 4419

Wireless Access Deployment Overview 4420
Wireless access deployment components 4421
802.1X-capable Wireless access points 4422
Active Directory Domain Services 4422
NPS 4424
Wireless client computers 4424
Wireless access deployment process 4424
Wireless Access Deployment Planning 4425
Planning wireless AP installations 4426
Verify wireless AP support for standards 4426
Identify areas of coverage for wireless users 4426
Determine where to install wireless APs 4427
Plan the configuration of wireless APs in NPS 4427
Plan the use of PEAP Fast Reconnect 4428
Wireless AP configuration 4428
Planning wireless client configuration and access 4430
Planning support for multiple standards 4431
Planning restricted access to the wireless network 4431
Planning methods for adding new wireless computers 4432
Wireless Access Deployment 4433
Deploying and Configuring Wireless APs 4433
Specify Wireless AP Channel Frequencies 4433
Configure Wireless APs 4433
Creating Security Groups for Wireless Users 4435
Create a Wireless Users Security Group 4435
Add Users to the Wireless Users Security Group 4435
Configuring Wireless Network (IEEE 802.11) Policies 4436
Open or Add and Open a Group Policy Object 4436
Activate Default Wireless Network (IEEE 802.11) Policies 4437
Open Wireless Network (IEEE 802.11) Policies for Editing 4438
Configure the New Wireless Network Policy 4439
Configure a Wireless Connection Profile for PEAP-MS-CHAP v2 4439
Set the Preference Order for Wireless Connection Profiles 4442
Define Network Permissions 4443
Configure the New Windows XP Wireless Network Policy 4444
To configure a Windows XP wireless connection profile for PEAP-MS-CHAP v2 4445
Configuring your NPS Server 4446
Register NPS in Active Directory Domain Services 4446
Configure a Wireless AP as an NPS RADIUS Client 4447
Create NPS Policies for 802.1X Wireless Using a Wizard 4448
Joining New Wireless Computers to the Domain 4451
Join the Domain and Log On by using Wireless Method 1 4452
Join the Domain and Log On by using Wireless Method 2 4453

Join the Domain and Log On by using Wireless Method 3 4455

Core Network Companion Guide: Deploying BranchCache Hosted Cache Mode 4479
- Prerequisites for using this guide 4480
- About this guide 4481
- What this guide does not provide 4481
- Technology overviews 4482
  - BranchCache 4482
  - Group Policy 4482

BranchCache Hosted Cache Mode Deployment Overview 4482
- Hosted Cache Server deployment components 4482
  - HCS1 in the branch office 4483
  - WEB1 in the cloud data center 4483
  - FILE1 in the cloud data center 4483
  - DC1 in the main office 4484
  - Client computers in the branch office 4484
- Hosted Cache Server deployment process overview 4484

BranchCache Hosted Cache Mode Deployment Planning 4485
- Plan basic server configuration 4485
- Plan domain access 4485
- Plan the location and size of the hosted cache 4486
- Plan the share to which the content server packages are to be copied 4486
- Plan prehashing and data package creation on content servers 4486

BranchCache Hosted Cache Mode Deployment 4486

Install the BranchCache Feature and Configure the Hosted Cache Server by Service Connection Point 4487

Move and Resize the Hosted Cache (Optional) 4488

Prehash and Preload Content on the Hosted Cache Server (Optional) 4489

Create Content Server Data Packages for Web and File Content (Optional) 4490

Import Data Packages on the Hosted Cache Server (Optional) 4491

Configure Client Automatic Hosted Cache Discovery by Service Connection Point 4492

Additional Resources 4493

Core Network Companion Guide: Group Policy Deployment 4494
About this guide 4494
Requirements 4495

Procedure: Review DNSSEC Parameters and Settings 4799
Review DNSSEC parameters and settings in DNS Manager 4800

Review DNSSEC parameters and settings in Windows PowerShell 4800
See also 4804

Procedure: Enable DNS Diagnostic Events 4804
In this section 4804
View and modify the event logging status 4804
See also 4808

Procedure: Review Key Rollover Status 4808
Review key rollover status in DNS Manager 4808
Review key rollover status in Windows PowerShell 4808
See also 4811

Checklist: Revert to an Unsigned Zone 4811
See also 4812

Procedure: Configure the NRPT 4812
Configure the NRPT with the Group Policy Management console 4813
Configure the NRPT with Windows PowerShell 4813
See also 4815

Procedure: Verify Name Resolution Policy 4815
Review NRPT configuration 4816
Review effective name resolution policy 4817
Verify DNSSEC validation 4818
See also 4823

Procedure: Remove a Trust Point 4823
Delete a trust point using DNS Manager 4824
Delete a trust point using Windows PowerShell 4824
See also 4825

Procedure: Unsign a Zone 4825
Unsign a zone in DNS Manager 4825
Unsign a zone in Windows PowerShell 4825
See also 4826

Procedure: Verify DNS Resolution 4826
Verify DNSSEC validation 4826
See also 4831

Checklist: Manage Signing Keys 4831
See also 4832

Procedure: Review Signing Keys 4832
Review DNSSEC signing keys in DNS Manager 4832

Review DNSSEC signing keys in Windows PowerShell 4833
See also 4835

Procedure: Retire a Signing Key 4836
Revoke a signing key using DNS Manager 4836
Revoke a signing key using Windows PowerShell 4837
See also 4838

Checklist: Move the Key Master Role 4838
See also 4838

Procedure: Move the Key Master Role 4839
Move the Key Master role using DNS Manager 4839
Move the Key Master role using Windows PowerShell 4840
See also 4841

Procedure: Seize the Key Master Role 4841
Seize the Key Master role using DNS Manager 4842
Seize the Key Master role using Windows PowerShell 4842
See also 4844

Checklist: Reconfigure Zone Signing Parameters on a Signed Zone 4844
See also 4845

Procedure: Modify Zone Signing Parameters 4845
Modify DNSSEC parameters and settings in DNS Manager 4845
Modify DNSSEC parameters and settings in Windows PowerShell 4846
See also 4848

Procedure: Review DNSSEC Parameters and Settings 4848
Review DNSSEC parameters and settings in DNS Manager 4849
Review DNSSEC parameters and settings in Windows PowerShell 4849
See also 4853

Checklist: Perform an Emergency Key Revocation 4853
See also 4853

Procedure: Import a Trust Point 4854
Import a trust point using DNS Manager 4854
Import a trust point using Windows PowerShell 4855
See also 4855

Procedure: Replace Signing Keys 4856
Replace a signing key using DNS Manager 4856
Replace a signing key using Windows PowerShell 4857
See also 4858

Checklist: Perform a Manual Key Rollover 4858
See also 4859

Procedure: Perform a Manual Signing Key Rollover 4859
Perform a manual signing key rollover using DNS Manager 4860
Perform a manual signing key rollover using Windows PowerShell 4860
See also 4862

Procedure: Review Key Rollover Status 4862
Review key rollover status in DNS Manager 4862
Review key rollover status in Windows PowerShell 4863
See also 4865

Checklist: Secure Zone Transfers 4866
See also 4866

Procedure: Deploy Certificates for DNS Server Authentication 4866
Configure certificate templates 4867
Publish certificate templates 4868
Enable certificate auto-enrollment 4869
See also 4869

Procedure: Deploy IPsec Policy to DNS Servers 4870
Configure IPsec policy 4870
Certificate Selection 4872
See also 4873

Appendix A: DNSSEC Terminology 4873

Appendix B: Windows PowerShell for DNS Server 4878

Step-by-Step: Demonstrate DNSSEC in a Test Lab 4890
In this guide 4890
DNSSEC overview 4891
DNS threats 4891
How DNSSEC works 4891
Digital signatures 4892
Zone signing 4892
Authenticated denial of existence 4892
Trust anchors 4892
DNSSEC key management 4892
DNSSEC-aware clients 4893
NRPT 4893
Scenario overview 4893
Hardware and software requirements 4894

Steps for configuring the test lab ... 4894
Configure DC1 ... 4894
Install the operating system and configure TCP/IP on DC1 ... 4895
Install Active Directory and DNS on DC1 ... 4895
Configure the sec.contoso.com DNS zone ... 4897
Enable Remote Desktop on DC1 ... 4898
Configure DNS1 ... 4898
Install the operating system and configure TCP/IP on DNS1 ... 4898
Install and configure DNS on DNS1 ... 4899
Optional: Install Network Monitor on DNS1 ... 4900
Configure DC2 ... 4900
Install the operating system and configure TCP/IP on DC2 ... 4901
Install Active Directory and DNS on DC2 ... 4901
Configure Client1 ... 4902
Install the operating system and configure TCP/IP on Client1 ... 4902
Join Client1 to the contoso.com domain ... 4903
Pin Windows PowerShell to the taskbar ... 4903
DNSSEC demonstration ... 4904
Query an unsigned zone without DNSSEC validation required ... 4904
Sign a zone on DC1 and distribute trust anchors ... 4905
Query a signed zone without DNSSEC validation required ... 4910
Query a signed zone with DNSSEC validation required ... 4911
Query DNSSEC records in the sec.contoso.com zone ... 4912
Unsign the zone and then re-sign the zone with custom parameters ... 4913
Demonstrate failed validation ... 4916
Demonstrate Remote Desktop failure ... 4917
Demonstrate Active Directory replication of DNSSEC signed resource records ... 4918
Transfer the Key Master role for sec.contoso.com to DC2 ... 4919
Appendix: Network Monitor results ... 4920
Packet capture results ... 4920

Dynamic Host Configuration Protocol (DHCP) Overview ... 4921
Role description ... 4921
Practical applications ... 4922
New and changed functionality ... 4922
Server Manager information ... 4922
See Also ... 4922

What's New in DHCP in Windows Server 2012 R2 ... 4923
Role/Feature description ... 4923
New and changed functionality ... 4923
DNS registration enhancements ... 4923
DNS PTR registration options ... 4924
Windows PowerShell for DHCP server ... 4924

What's New in DHCP in Windows Server 2012 4927
Role/Feature description 4927
New and changed functionality 4927
See Also 4927

Understand and Deploy DHCP Failover 4928
DHCP high availability options 4928
In this guide 4929
See Also 4930

What is DHCP Failover? 4930
Introduction to DHCP failover 4931
DHCP failover specifications 4932
DHCP failover and IPv6 4933
DHCP failover and Windows Failover Clustering 4933
DHCP failover and DNS dynamic updates 4934
See also 4935

DHCP Failover Relationships 4935
Understand failover relationships 4935
Create failover relationships 4937
View failover relationships 4938
Edit failover relationships 4940
Delete failover relationships 4941
See also 4942

DHCP Failover Modes 4943
Hot standby mode 4943
Load balance mode 4944
See also 4945

DHCP Failover Communications 4945
DHCP failover messages 4946
See also 4949

DHCP Failover Settings 4949
Name 4951
Partner server 4951
Mode 4951
Load balance percentage 4951
Server role 4951
Reserve percentage 4951
Maximum client lead time (MCLT) 4952
State switchover interval 4952
State 4952

Scope IDs ... 4955
Automatic state transition ... 4955
Enable authentication ... 4955
See also ... 4955

DHCP Failover Examples ... 4956
Hot standby example ... 4956
Load balancing example ... 4958
Partner down example ... 4960
See also ... 4962

DHCP Failover Events and Performance ... 4962
DHCP server event channels ... 4962
Administrative event logging ... 4963
Operational event logging ... 4965
Performance counters ... 4968
See also ... 4968

Deploy DHCP Failover ... 4969
Overview: Configure DHCP failover using the DHCP console ... 4969
Overview: Configure DHCP failover using Windows PowerShell ... 4970
See also ... 4970

DHCP Failover Requirements ... 4970
Prerequisite checks ... 4973
See also ... 4974

DHCP Failover Architecture ... 4974
DHCP failover design ... 4974
Hot standby design ... 4974
Load balance design ... 4975
Load balance in a single site with a single subnet ... 4975
Load balance in a single site with multiple subnets ... 4976
Deployment considerations ... 4977
Time synchronization ... 4977
BOOTP support ... 4977
Policy based assignment ... 4977
Windows Firewall ... 4978
Relay agents ... 4978
Duplicate relay agents ... 4978
See also ... 4979

Checklist: Deploy DHCP Failover ... 4979
See also ... 4980

Configure DHCP Failover using the Command Line ... 4980
Configure DHCP failover in load balance mode using the command line ... 4981
Configure DHCP failover in hot standby mode using the command line ... 4982
See also ... 4983

Configure DHCP Failover using the DHCP Console ... 4983
Configure DHCP failover in load balance mode using the DHCP console ... 4984
Configure DHCP failover in hot standby mode using the DHCP console ... 4987
See also ... 4988

Replicate DHCP Failover Using the Command Line ... 4989
Replicate failover settings at the server level using the command line ... 4989
Replicate failover settings at the relationship level using the command line ... 4990
Replicate failover settings at the scope level using the command line ... 4991
See also ... 4991

Replicate DHCP Failover Using the DHCP Console ... 4991
Replicate failover settings at the server level using the DHCP console ... 4992
Replicate failover settings at the relationship level using the DHCP console ... 4992
Replicate failover settings at the scope level using the DHCP console ... 4993
See also ... 4993

Migrate to DHCP Failover ... 4993
Migrate to DHCP failover ... 4994
Install the DHCP Server role on DHCP2012-1 and DHCP2012-2 ... 4994
Export DHCP settings and leases from DHCP2008-1 and DHCP2008-2 ... 4995
Import DHCP settings and leases to DHCP2012-1 ... 4998
Import server level settings to DHCP2012-2 ... 4999
Configure DHCP failover on DHCP2012-1 ... 4999
Update DHCP relay agents and complete migration ... 4999
See also ... 4999

DHCP Policy Based Assignment (PBA) Scenario Guide ... 4999
In this guide ... 5000
See also ... 5000

Introduction to DHCP Policies ... 5000
Why DHCP PBA? ... 5000
How DHCP PBA works ... 5002
DHCP policy conditions and settings ... 5005
Conditions ... 5005
Settings ... 5006
Policy processing ... 5007
Deploying DHCP policies ... 5008
See also ... 5009

Scenario: Manage the network configuration of virtual machines 5009
Problem description 5009
Virtual machines 5010
MAC addressing in Hyper-V 5011
Configure a MAC address based DHCP policy 5012
Conclusion 5013
See also 5013

Scenario: Secure a subnet to a specific set of clients 5013
Problem description 5013
Creating a scope-based allow-filter list using DHCP policies 5014
Creating a scope-based deny-filter list using DHCP policies 5016
Windows PowerShell 5017
See also 5018

Scenario: Customize lease duration based on device type 5018
Problem description 5018
Grouping devices on the network 5019
Configure DHCP policies for different lease durations 5019
Use Windows PowerShell to configure policies with different lease duration 5024
See also 5024

Step-by-Step: Configure DHCP Using Policy-based Assignment 5025
In this guide 5025
DHCP policy based assignment overview 5025
Policy settings and evaluation 5026
Address assignment 5026
Option assignment 5027
Scenario overview 5027
Hardware and software requirements 5027
Steps for configuring the test lab 5028
Configure DHCP1 5028
Install the operating system and configure TCP/IP on DHCP1 5028
Install AD DS, DNS Server, and DHCP Server 5029
Create a domain administrator account 5030
Create a DHCP scope on DHCP1 5031
Configure Client1 5032
Install the operating system on Client1 5032
Pin Windows PowerShell to the taskbar 5032
Configure Client2 5033
DHCP policy based assignment demonstration 5033
Determine MAC addresses 5033
Create policies 5034
Demonstrate policies 5036

Step-by-Step: Configure DHCP for Failover ... 5038
In this guide ... 5038
DHCP failover overview ... 5038
DHCP failover architecture ... 5039
Hot standby mode ... 5039
Load sharing mode ... 5040
Load sharing in a single site with a single subnet ... 5040
Load sharing in a single site with multiple subnets ... 5041
Scenario overview ... 5041
Hardware and software requirements ... 5042
Steps for configuring the test lab ... 5042
Configure DHCP1 ... 5043
Install the operating system and configure TCP/IP on DHCP1 ... 5043
Install AD DS, DNS Server, and DHCP Server ... 5044
Create a domain administrator account ... 5045
Authorize DHCP1 in Active Directory ... 5046
Configure DHCP2 ... 5046
Install the operating system and configure TCP/IP on DHCP2 ... 5046
Install and configure DHCP on DHCP2 ... 5047
Configure Client1 ... 5049
Install the operating system on Client1 ... 5049
Pin Windows PowerShell to the taskbar ... 5049
DHCP failover demonstration ... 5050
Configure a failover relationship ... 5050
View or edit properties of the failover configuration ... 5052
Edit properties of the failover relationship and demonstrate load balancing ... 5054
Edit properties of the failover relationship and demonstrate hot standby mode ... 5055
Conclusion ... 5056

Test Lab Guide: Demonstrate DirectAccess in a Cluster with Windows NLB ... 5625
About this guide ... 5625
Known issues ... 5625

Overview of the Test Lab Scenario ... 5626

Configuration Requirements 5627
Steps for Configuring the Test Lab 5628
STEP 1: Complete the DirectAccess Configuration 5628
STEP 2: Configure EDGE1 5628
STEP 3: Install and Configure EDGE2 5629
STEP 4: Create the Network Load Balanced Remote Access Cluster 5632
Prerequisites 5632
Install the Network Load Balancing feature on EDGE1 and EDGE2 5633
Enable load balancing on EDGE1 5633
Add EDGE2 to the load balanced cluster 5634
STEP 5: Test DirectAccess Connectivity from the Internet and Through the Cluster 5635
STEP 6: Test DirectAccess Client Connectivity from Behind a NAT Device 5637
Prerequisites 5638
STEP 7: Test Connectivity When Returning to the Corpnet 5640
STEP 8: Snapshot the Configuration 5640
Test Lab Guide: Demonstrate a DirectAccess Multisite Deployment 5641
About this guide 5641
Overview of the Test Lab Scenario 5641
Configuration Requirements 5643
Steps for Configuring the Test Lab 5644
STEP 1: Complete the DirectAccess Configuration 5645
STEP 2: Install and Configure ROUTER1 5645
Install the operating system on ROUTER1 5645
Configure TCP/IP properties and rename the computer 5645
Turn off the firewall 5646
Configure routing and forwarding 5647
STEP 3: Install and Configure CLIENT2 5648
User account control 5648
STEP 4: Configure APP1 5649
STEP 5: Configure DC1 5649
Create security groups for Windows 7 DirectAccess clients on DC1 5651

STEP 6: Install and Configure 2-DC1 5651
Install the operating system on 2-DC1 5652
Configure TCP/IP properties 5652
Configure 2-DC1 as a domain controller and DNS server 5653
Provide Group Policy permissions to CORP\User1 5654
Allow CORP2 computers to obtain computer certificates 5654
Force replication between DC1 and 2-DC1 5655

STEP 7: Install and Configure 2-APP1 5656
Install the operating system on 2-APP1 5656
Configure TCP/IP properties 5656
Join 2-APP1 to the CORP2 domain 5657
Install the Web Server (IIS) role on 2-APP1 5657
Create a shared folder on 2-APP1 5658

STEP 8: Configure INET1 5658

STEP 9: Configure EDGE1 5659

STEP 10: Install and Configure 2-EDGE1 5659

STEP 11: Configure the Multisite Deployment 5663

STEP 12: Test DirectAccess Connectivity 5665
Prerequisites 5665

STEP 13: Test DirectAccess Connectivity from Behind a NAT Device 5669
Prerequisites 5670

STEP 14: Snapshot the Configuration 5672

Test Lab Guide: Demonstrate DirectAccess with OTP Authentication and RSA SecurID 5672
About this guide 5672

Overview of the Test Lab Scenario 5673

Configuration Requirements 5674

Steps for Configuring the Test Lab 5675

STEP 1: Complete the DirectAccess Configuration 5675

STEP 2: Configure APP1 5675

STEP 3: Configure DC1 5678

STEP 4: Install and Configure RSA and EDGE1 5678
Install RSA SecurID software token on CLIENT1 5682
Configure EDGE1 as an RSA Authentication Agent 5683

Configure EDGE1 to support OTP authentication 5683
STEP 5: Verify OTP Health on EDGE1 5684
STEP 6: Test DirectAccess Connectivity from the Homenet Subnet 5685
STEP 7: Test DirectAccess Connectivity from the Internet 5686
STEP 8: Snapshot the Configuration 5687
Deploy Remote Access in a Cluster 5687
Windows Server 2012 Remote Access (DirectAccess) Deployment Documentation Set 5687
Deploy Basic Remote Access 5687
Deploy Advanced Remote Access 5687
Deploy Remote Access in an Enterprise 5688
Manage Remote Access 5688
Migrate Remote Access 5688
Scenario description 5688
Prerequisites 5688
In this scenario 5689
Practical applications 5689
Roles and features included in this scenario 5689
Hardware requirements 5691
Software requirements 5691
Known issues 5692
Plan a Remote Access Cluster Deployment 5693
Step 1: Plan an Advanced Single-Server Deployment 5693
Plan a single server deployment 5693
Step 2: Plan Cluster Servers 5693
2.1 Installing roles and features 5694
2.2 Configure server settings 5694
See also 5694
Step 3: Plan a Load-Balanced Cluster Deployment 5695
3.1 Plan load balancing 5695
3.1.1 External Load Balancer configuration example 5696
3.2 Plan IP-HTTPS 5698
3.3 Plan for VPN client connections 5698
3.4 Plan the network location server 5698
See also 5699
Configure a Remote Access Cluster 5699
Step 1: Implement a Single-Server Remote Access Deployment 5699

Implement a single server deployment ... 5699
See also ... 5699

Step 2: Prepare Cluster Servers ... 5700
2.1 Configure the Remote Access infrastructure ... 5700
2.2 Install the Remote Access role ... 5701
2.3 Install NLB ... 5701
See also ... 5701

Step 3: Configure a Load-Balanced Cluster ... 5701
3.1 Configure the IPv6 prefix ... 5703
3.2 Enable load balancing ... 5703
3.3 Install the IP-HTTPS certificate ... 5705
3.4 Install the network location server certificate ... 5706
3.5 Add servers to the cluster ... 5707
3.6 Remove a server from the cluster ... 5708
3.7 Disable load balancing ... 5709
3.8 Change from unicast to multicast ... 5710
See also ... 5710

Step 4: Verify the Cluster ... 5710

Deploy Multiple Remote Access Servers in a Multisite Deployment ... 5711
Windows Server 2012 Remote Access (DirectAccess) Deployment Documentation Set ... 5711
Deploy Basic Remote Access ... 5711
Deploy Advanced Remote Access ... 5711
Deploy Remote Access in an Enterprise ... 5711
Manage Remote Access ... 5712
Migrate Remote Access ... 5712
Scenario description ... 5712
Prerequisites ... 5712
In this scenario ... 5713
Practical applications ... 5713
Roles and features included in this scenario ... 5713
Hardware requirements ... 5715
Software requirements ... 5715
Known issues ... 5716

Plan a Multisite Deployment ... 5718

Step 1: Plan an Advanced Single Server Deployment ... 5718
Plan a single server deployment ... 5719
See also ... 5719

Step 2: Plan the Multisite Infrastructure ... 5719

2.1 Plan Active Directory ... 5719
Active Directory best practices and recommendations ... 5721
2.2 Plan security groups ... 5722
2.3 Plan Group Policy Objects ... 5723
2.3.1 Automatically-created GPOs ... 5723
2.3.2 Manually created GPOs ... 5724
2.3.3 Managing GPOs in a multi-domain controller environment ... 5724
Modifying domain controller association ... 5725
2.4 Plan DNS ... 5726
See also ... 5726

Step 3: Plan the Multisite Deployment ... 5727
3.1 Plan IP-HTTPS certificates ... 5727
3.2 Plan the network location server ... 5728
3.2.1 Certificate requirements for the network location server ... 5728
3.2.2DNS for the network location server ... 5729
3.3 Plan the IPsec root certificate for all Remote Access servers ... 5729
3.4 Plan global server load balancing ... 5729
3.5 Plan DirectAccess client entry point selection ... 5730
3.6 Plan prefixes and routing ... 5731
Internal IPv6 prefix ... 5731
IPv6 prefix for DirectAccess client computers (IP-HTTPS prefix) ... 5731
IPv6 prefix for VPN clients ... 5731
Routing ... 5731
Active Directory site-specific IPv6 prefixes ... 5733
3.7 Plan the transition to IPv6 when multisite Remote Access is deployed ... 5733
Transition from an IPv4-only to an IPv6+IPv4 corporate network ... 5734
Transition from an IPv6+IPv4 to an IPv6-only corporate network ... 5734
Transition from an IPv4-only to an IPv6-only deployment using dual DirectAccess deployments ... 5735
See also ... 5736

Configure a Multisite Deployment ... 5736

Step 1: Implement a Single Server Remote Access Deployment ... 5736
Implement a single server deployment ... 5737
See also ... 5737

Step 2: Configure the Multisite Infrastructure ... 5737
2.1. Configure additional Active Directory sites ... 5737
2.2. Configure additional domain controllers ... 5739
2.3. Configure security groups ... 5740
2.4. Configure GPOs ... 5741
Domain controller maintenance and downtime ... 5742

Change two or more domain controllers that manage server GPOs 5743
Optimization of configuration distribution 5746
See also 5747

Step 3: Configure the Multisite Deployment 5747
3.1. Configure Remote Access servers 5748
3.2. Grant administrator access 5749
3.3. Configure IP-HTTPS for a multisite deployment 5749
3.4. Configure the network location server for a multisite deployment 5750
3.5. Configure DirectAccess clients for a multisite deployment 5752
3.6. Enable the multisite deployment 5753
3.7. Add entry points to the multisite deployment 5755
See also 5757

Step 4: Verify the Multisite Deployment 5757

Troubleshoot a Multisite Deployment 5758

Troubleshooting Enabling Multisite 5759
User connectivity issues 5759
Kerberos proxy authentication 5759
IP-HTTPS certificates 5760
Network location server 5760
Windows 7 client computers 5761
Active Directory site 5761
Saving server GPO settings 5762
Internal error occurred 5762

Troubleshooting Adding Entry Points 5762
Internal error occurred 5763
Missing RemoteAccessServer parameter 5763
Remote Access is not configured 5763
Multisite not enabled 5763
IPv6 prefix issues 5764
ConnectTo address 5764
DirectAccess or VPN already installed 5765
IPsec root certificate 5765
Mixing IPv6 and IPv4 entry points 5766
Domain issues with the ServerGpoName 5767
Split-brain DNS 5768
Saving server GPO settings 5768
GPO updates cannot be applied 5768

Troubleshooting Setting the Entry Point Domain Controller 5769
Saving server GPO settings 5769

Remote Access is not configured ... 5769
Multisite is not enabled ... 5769
Entry point and domain controller not provided in cmdlet ... 5770
Could not locate domain controller ... 5770
Could not connect to domain controller ... 5771
Read-only domain controller ... 5772
Cannot retrieve GPO ... 5772
Entry point not part of multisite deployment ... 5773
Remote Access server settings ... 5773
Problem resolving FQDN ... 5774
No entry points to update ... 5774

Troubleshooting Web Probe URLs ... 5775
Adding and removing web probe URLs ... 5775
IP address of management server associated with web probe URL ... 5775
Cannot verify IP addresses ... 5776
DNS entry cannot be updated ... 5776

Troubleshooting General Issues ... 5776
GPO retrieval error ... 5776
Windows 7 to Windows 8 client upgrade ... 5777
General cmdlet errors ... 5778

Deploy Remote Access with OTP Authentication ... 5778
Windows Server 2012 Remote Access (DirectAccess) Deployment Documentation Set ... 5779
Deploy Basic Remote Access ... 5779
Deploy Advanced Remote Access ... 5779
Deploy Remote Access in an Enterprise ... 5779
Manage Remote Access ... 5779
Migrate Remote Access ... 5779
Scenario description ... 5780
Prerequisites ... 5780
In this scenario ... 5780
Practical applications ... 5781
Roles and features included in this scenario ... 5781
Hardware requirements ... 5782
Software requirements ... 5783
Known Issues ... 5784

Plan Remote Access with OTP Authentication ... 5784

Step 1: Plan an Advanced Single Server Deployment ... 5785
Plan a single server deployment ... 5785

Step 2: Plan the RADIUS Server Deployment ... 5785

2.1 Plan the RADIUS server ... 5785
See also ... 5786

Step 3: Plan OTP Certificate Deployment ... 5786
3.1 Plan the OTP CA ... 5786
3.2 Plan the OTP certificate template ... 5787
3.3 Plan the registration authority certificate ... 5787
See also ... 5788

Step 4: Plan for OTP on the Remote Access Server ... 5788
4.1 Plan for OTP client exemptions ... 5788
4.2 Plan for Windows 7 clients ... 5788
4.3 Plan for smart cards ... 5789
See also ... 5789

Configure DirectAccess with OTP Authentication ... 5789

Step 1: Implement a Single Server Remote Access Deployment ... 5789
Implement a single server deployment ... 5789
See also ... 5790

Step 2: Configure the RADIUS Server ... 5790
2.1 Configure the RADIUS software distribution tokens ... 5790
2.2 Configure the RADIUS security information ... 5790
2.3 Adding user account for OTP probing ... 5791
2.4 Synchronize with Active Directory ... 5791
2.5 Configure the RADIUS authentication agent ... 5791

Step 3: Configure the Remote Access Server for OTP ... 5791
3.1 Exempt users from OTP authentication (optional) ... 5792
3.2 Configure the Remote Access server to support OTP ... 5792
3.3 Smart cards for additional authorization ... 5794
Allowing access for users with unusable smart cards ... 5795
Under the covers: Smart card authorization ... 5795

Step 4: Verify DirectAccess with OTP ... 5795

Troubleshoot an OTP Deployment ... 5796

Troubleshooting Authentication Issues ... 5797
Failed to access the CA that issues OTP certificates ... 5797
DirectAccess server connectivity issues ... 5797
Failed to enroll for the DirectAccess OTP logon certificate ... 5798
Missing or invalid computer account certificate ... 5798
Missing CA that issues OTP certificates ... 5799
Misconfigured DirectAccess server address ... 5799

Failed to generate the OTP logon certificate request 5800
No connection to the domain controller 5800
OTP provider requires challenge/response 5801
Incorrect OTP logon template used 5801
Missing OTP signing certificate 5801
Missing or incorrect UPN/DN for the user 5802
OTP certificate is not trusted for login 5802
Windows could not verify user credentials 5803

Troubleshooting Enabling OTP 5803
Failed to enroll the OTP signing certificate 5804
Failed to enable DirectAccess OTP when WebDAV is installed 5804
No templates available in the Remote Access Management console 5805
Cannot set renewal period of OTP template to 1 hour 5805

Deploy Remote Access in a Multi-Forest Environment 5806

Plan a Multi-Forest Deployment 5806
Prerequisites 5806
Plan trust between forests 5806
Plan Remote Access administrator permissions 5806
Plan client security groups 5807
Plan certification authorities 5807
Plan OTP exemptions 5808

Configure a Multi-Forest Deployment 5808
Access resources from Forest2 5808
Enable clients from Forest2 to connect via DirectAccess 5808
Add entry points from Forest2 5809
Configure OTP in a multi-forest deployment 5809
Configuration procedures 5811
Add NRPT rules and DNS suffixes 5811
Add internal IPv6 prefix 5812
Add client security groups 5813
Refresh the management servers list 5813

Deploy Remote Access in the Cloud 5814
Scenario description 5814
In this scenario 5814
Practical applications 5815
Cloud Bursting 5815
Disaster Recovery 5815
Roles and features included in this scenario 5816
Hardware requirements 5817
Software requirements 5817

Test Lab Guide : Corp to Cloud: Configure an IKEv2-based Site-to-site VPN Connection 5818
About this guide 5818

Overview of the test lab scenario 5819

Configuration component requirements 5821

Steps for configuring the test lab 5821

STEP 1: Complete the base configuration 5821
STEP 1: Complete the Base Configuration 5821

STEP 2: Install and Configure 3-EDGE1 5822
STEP 2: Install and Configure 3-EDGE1 5822

STEP 3: Configure routing and forwarding between EDGE-1 and 3-EDGE1 using pre-shared key authentication 5824
STEP 3: Configure routing and forwarding between EDGE1 and 3-EDGE1 using EAP and (optionally) preshared key authentication 5824

STEP 4: Install a basic PKI certificate infrastructure 5829
Step 4: Install a basic PKI certificate infrastructure for site-to-site certificate authentication method. 5829

STEP 5: Configure EDGE1 and 3-EDGE1 to use EAP for site-to-site authentication 5839

STEP 6: Configure EDGE1 and 3-EDGE1 to use certificates for site-to-site authentication 5840
Configure computer certificate authentication on EDGE1 5840
Configure name resolution 5841
Export the root certificate (corp-DC1-CA) from EDGE1 5841
Configure computer certificate authentication on 3-EDGE1 5842
Configure name resolution 5842
Export the root certificate (corp-3-DC1-CA) from 3-EDGE1 5843
Import the root certificate (corp-DC1-CA) to 3-EDGE1 5843
Change the authentication method to certificates on EDGE1 5844
Change the authentication method to certificates on 3-EDGE1 5844
Reinitiate the site-to-site connection 5845
Test the site-to-site connection 5845

Snapshot the configuration 5845

Manage Remote Access 5846
Scenario description 5846
In this scenario 5846
Plan the deployment 5846

Configure the deployment ... 5847
Practical applications ... 5847
Roles and features included in this scenario ... 5848
Hardware requirements ... 5849
Server requirements ... 5849
Client requirements ... 5849
Infrastructure and management server requirements ... 5849
Software requirements ... 5850
Server requirements ... 5850
Remote access client requirements ... 5850
See also ... 5850

Use Remote Access Monitoring and Accounting ... 5851
In this guide ... 5851
Understand monitoringand accounting ... 5851

Monitor the existing load on the Remote Access server ... 5852

Monitor the configuration distribution status of the Remote Access server ... 5853

Monitor the operations status of the Remote Access server and its components ... 5856

Identify and resolve Remote Access server operations problems ... 5857
Simulate an operations issue ... 5858
Identify the operations issue and take corrective action ... 5858
Restore the IP Helper service ... 5859

Monitor connected remote clients for activity and status ... 5859

Generate a usage report for remote clients using historical data ... 5861

Manage DirectAccess Clients Remotely ... 5863
Scenario description ... 5863
In this scenario ... 5863
Planning steps ... 5863
Prerequisites ... 5864
Deployment steps ... 5864
Practical applications ... 5864
Roles and features included in this scenario ... 5865
Hardware requirements ... 5866
Software requirements ... 5867
See also ... 5867

Plan Deployment for Remote Management of DirectAccess Clients ... 5868
Next steps ... 5869

Step 1: Plan the Remote Access Infrastructure ... 5869
Plan network topology and settings ... 5870
Plan network adapters and IP addressing ... 5870
Plan ISATAP requirements ... 5874
Plan firewall requirements ... 5878
Plan certificate requirements ... 5879
Plan computer certificates for IPsec authentication ... 5880
Plan certificates for IP-HTTPS ... 5880
Plan website certificates for the network location server ... 5881
Plan DNS requirements ... 5881
DirectAccess client requests ... 5881
Infrastructure servers ... 5882
Connectivity verifiers ... 5882
DNS server requirements ... 5883
Plan for local name resolution ... 5883
NRPT ... 5883
Single label names ... 5884
Split-brain DNS ... 5884
Plan local name resolution behavior for DirectAccess clients ... 5885
Plan the network location server configuration ... 5885
Plan certificates for the network location server ... 5886
Plan DNS for the network location server ... 5886
Plan management servers' configuration ... 5886
Plan Active Directory requirements ... 5887
Plan client authentication ... 5888
Plan multiple domains ... 5888
Plan Group Policy Object creation ... 5889
Automatically created GPOs ... 5889
Manually created GPOs ... 5890
Recovering from a deleted GPO ... 5890
See also ... 5890

Step 2: Plan the Remote Access Deployment ... 5891
Plan a client deployment strategy ... 5891
Plan a Remote Access server deployment strategy ... 5892
Plan the infrastructure servers' configurations ... 5894
See also ... 5894

Install and Configure Deployment for Remote Management of DirectAccess Clients ... 5894
See also ... 5895

Step 1: Configure the Remote Access Infrastructure ... 5895
Configure server network settings ... 5896
Configure routing in the corporate network ... 5897

Configure firewalls ... 5897
Remote Access server on IPv4 Internet ... 5897
Remote Access server on IPv6 Internet ... 5897
Remote Access traffic ... 5898
Configure CAs and certificates ... 5898
Configure IPsec authentication ... 5898
Configure certificate templates ... 5898
Configure the IP-HTTPS certificate ... 5899
Configure the DNS server ... 5900
Configure Active Directory ... 5901
Configure GPOs ... 5903
Configure security groups ... 5903
Configure the network location server ... 5904
See also ... 5906

Step 2: Configure the Remote Access Server ... 5906
Install the Remote Access role ... 5907
Configure the deployment type ... 5907
Configure DirectAccess clients ... 5908
Configure the Remote Access server ... 5909
Configure the infrastructure servers ... 5910
Configure application servers ... 5910
Configuration summary and alternate GPOs ... 5910
See also ... 5911

Step 3: Verify the Deployment ... 5911

Deploy VPN When Connecting Remotely with Windows 8 ... 5912
Deploy Windows 8 VPN client ... 5912
Use self-service portal ... 5912
Use Windows PowerShell scripts ... 5913
Advanced scenarios ... 5914
Use Connection Manager Administration Kit ... 5915
Manage profiles ... 5915
Connect VPN by using Windows 8 user interface ... 5917
Launch Windows 8 user interface for VPN connections ... 5918
Connect to VPN ... 5918
Deploy the VPN ... 5919
Password-based deployment ... 5919
Certificate-based deployments ... 5919
Enable split tunneling ... 5920
Understand route implications ... 5920
Deploy web proxy and intranet settings ... 5921
Deploy multisite VPN ... 5922

Interoperate with third-party VPN servers 5922
Use Connected Standby state 5922
Appendix A: Glossary 5922
Experience terminology 5923

Manage VPN Connections in Windows 8 by Using Windows PowerShell 5924
Use VPN deployment and management scripts: For IT pros 5925
Create VPN connections 5925
Configure and edit VPN connections 5926
New-EapConfiguration 5926
VPN connection lookup 5927
VPN connection removal 5927
Write configuration scripts for VPN connection management 5927
Use VPN deployment and management scripts: For knowledge workers 5931
Use Windows PowerShell cmdlets for third-party EAP methods 5932

Set Up and Edit VPN Connections in Windows 8 5932
Create a new VPN connection 5933
Discovery Profile 5933
Connect to a corporate network by use an existing VPN connection 5934
Edit connection properties 5938
Delete a connection 5939

VPN Compatibility and Interoperability in Windows 8 and Windows Server 2012 5940

Windows Server 2012 R2 Test Lab Guide: Demonstrate VPN Auto trigger 5940
In this Guide 5941
Test Lab Overview 5941
Hardware and software requirements 5942
Steps for Configuring the Remote Access VPN Auto-trigger Test Lab 5942
Step 1: Set up the Base Configuration Test Lab 5943
Step 2: Configure EDGE1 5943
Deploy VPN access using the Remote Access Configuration wizard 5943
Step 3: Configure INET1 5944
Create a new DNS host record on INET1 5945
Step 4: Add and Configure CLIENT2 5945
Install the operating system on CLIENT2 5945
Connect CLIENT2 to the Internet subnet and configure remote access with VPN 5946
Configure and test VPN auto-trigger functionality on CLIENT2 5946
Connect CLIENT2 to the Corpnet subnet and verify that auto-trigger functionality is disabled 5948
Snapshot the Configuration 5949

Deploy and Configure a VPN for Devices Running Windows RT 5949
Work with third-party VPN servers 5949

Verify third-party VPN interoperability ... 5950
VPN deployment options ... 5951
Multi-site VPN deployment ... 5951
Windows RT VPN client provisioning ... 5951
Get Connected Wizard (GCW) ... 5951
Single-Click (PowerShell) scripts ... 5952
Provisioning via System Center ... 5952
Profile management ... 5953
Enabling split-tunneling ... 5954
Implications on routes ... 5954
Provisioning web proxy and Intranet settings for VPN connection ... 5954
Connect to the VPN ... 5955
Use one-time password for authentication ... 5955

Migrate Remote Access to Windows Server 2012 ... 5956
About this guide ... 5957
Target audience ... 5957
What this guide does not provide ... 5957
Supported migration scenarios ... 5958
Supported operating systems ... 5958
Supported role configurations ... 5959
Migration dependencies ... 5959
Migration components that are not supported in all operating system versions ... 5959
Migration components that are not automatically migrated ... 5962
Overview of the Routing and Remote Access service migration process ... 5964
Impact of migration ... 5964
Permissions required to complete migration ... 5965
Estimated duration ... 5965
See Also ... 5966

Remote Access: Prepare to Migrate ... 5966
Prepare your destination server ... 5966
Hardware requirements for the destination server ... 5966
Prepare the destination server for migration ... 5967
Prepare your source server ... 5968
Back up your source server ... 5968
Install the migration tools ... 5968
See Also ... 5969

Remote Access: Migrate Remote Access ... 5969
Migrating Remote Access from the source server ... 5969
Migrating Remote Access to the destination server ... 5973
Completing the required manual migration steps ... 5974
DirectAccess ... 5974

Dial-up demand-dial connections ... 5974
Certificates for IKEv2, SSTP, and L2TP/IPsec connections ... 5975
Routing and Remote Access service policies and accounting settings ... 5975
PEAP, smart card, and other certificate settings on Network Policy Server ... 5975
Weak encryption settings ... 5975
Connection Manager profiles ... 5976
Group forwarded fragments ... 5976
RAS administration and security DLLs ... 5976
See Also ... 5976

Remote Access: Verify the Migration ... 5977
Verifying the destination server configuration ... 5977
Installation state of Remote Access ... 5977
Status of Remote Access Service ... 5977
Remote access Operations Status ... 5978
DirectAccess configuration ... 5978

Migrate from Forefront UAG SP1 DirectAccess to Windows Server 2012 ... 5989
Windows Server 2012 Remote Access (DirectAccess) Deployment Documentation Set ... 5989
Deploy Basic Remote Access ... 5990
Deploy Advanced Remote Access ... 5990
Deploy Remote Access in an Enterprise ... 5990
Manage Remote Access ... 5990

Migrate Remote Access ... 5990
Before you begin deploying, see the list of unsupported configurations, known issues, and prerequisites ... 5990
Scenario description ... 5991
In this scenario ... 5991
Prerequisites ... 5991
Practical applications ... 5991
Hardware requirements ... 5992
Software requirements ... 5992
Using ISATAP ... 5993
Using NAP ... 5993

Side-by-Side Migration of Forefront UAG DirectAccess ... 5993

Side-by-Side Migration Steps ... 5994
Step 1: Configure ISATAP ... 5995
Step 2: Export the Forefront UAG DirectAccess settings ... 5999
Step 3: Collect Forefront UAG DirectAccess GPO settings ... 5999
Step 4: Install the Remote Access role ... 5999
Step 5: Configure server and infrastructure settings ... 6000
Step 6: Obtain an IP-HTTPS certificate ... 6000
Step 7: Create a security group for DirectAccess clients ... 6000
Step 8: Prepare GPOs ... 6000
Step 9: Configure DirectAccess ... 6001
See also ... 6004

Offline Migration of Forefront UAG DirectAccess ... 6004

Offline Migration Steps ... 6005
Step 1: Install the Remote Access role ... 6006
Step 2: Configure IP addresses ... 6006
Step 3: Obtain an IP-HTTPS certificate ... 6007
Step 4: Prepare GPOs ... 6007
Step 5: Configure DirectAccess ... 6007
See also ... 6007

Connection Manager Overview ... 6007

Connection Manager Administration Kit Overview ... 6008

Add DirectAccess to an Existing Remote Access (VPN) Deployment ... 6008

Authentication and Authorization ... 6043
Authenticating Users and Devices ... 6044
Authentication Capabilities ... 6045
Web Application Proxy Technical Overview ... 6045
Web Application Proxy Configuration Storage ... 6046
AD FS Proxy Functionality ... 6046
Managing Web Application Proxy ... 6047
Interoperability with Other Remote Access Products ... 6047

Overview: Connect to Applications and Services from Anywhere with Web Application Proxy 6048
Providing Access to Applications and Services ... 6049
Using Active Directory Federation Services ... 6049
AD FS Proxy ... 6050
Roles and Features Included in this Scenario ... 6050
Scenario Steps ... 6050
See Also ... 6051

Walkthrough Guide: Connect to Applications and Services from Anywhere with Web Application Proxy ... 6051

Step 1: Attempt to access the web application from an Internet client 6053
Step 2: Configure the Web Application Proxy server and publish the application 6054
Step 3: Configure and test accessing a website using Integrated Windows authentication .. 6057
Install Windows Authentication on WebServ1 6057
Create a new website using IIS 6057
Create a non-claims-aware relying party trust 6058
Configure Kerberos constrained delegation 6059
Test accessing the application internally 6060
Publish the application 6060
Test accessing the application 6061
Step 4: Demonstrate accessing an application using Workplace Join, MFA, and multifactor access control 6061
See also 6063

Installing and Configuring Web Application Proxy for Publishing Internal Applications 6063
Providing Access to Applications and Services 6064
Roles and Features Included in this Scenario 6064
Scenario Steps 6064
Hardware requirements 6065
Software requirements 6065
Known issues 6065

Plan to Publish Applications through Web Application Proxy 6066

Step 1: Plan the Web Application Proxy Infrastructure 6067
1.1. Plan Network Location 6067
Plan Firewalls 6068
1.2. Plan DNS 6068
1.3. Plan Load Balancing 6068
1.4. Plan Active Directory 6069
Plan Integrated Windows authentication and Kerberos constrained delegation 6069
1.5. Plan Active Directory Federation Services 6070
AD FS Requirements 6070
1.6. Plan Preauthentication 6070
See also 6071

Step 2: Plan the Web Application Proxy Server 6071
2.1. Plan the Web Application Proxy Role Service Installation 6071
2.2. Plan Multiple Servers 6072
2.3. Plan Certificates 6072
2.4. Plan NTP 6074
See also 6074

Step 3: Plan to Publish Applications using AD FS Preauthentication 6074
3.1. Plan Claims-Based Applications 6076

3.2. Plan Integrated Windows Authentication-Based Applications 6076
3.3. Plan Applications for MSOFBA Clients 6077
3.4. Plan Applications for Clients that use Windows Store Apps 6078
See also 6079

Step 4: Plan to Publish Applications using Client Certificate Preauthentication 6080
4.1. Plan the External Servers 6080
4.2. Plan Applications for Client Certificate Preauthentication 6081
See also 6081

Step 5: Plan to Publish Applications using Pass-through Preauthentication 6081
5.1. Plan Applications for Pass-Through Preauthentication 6082
See also 6082

Step 6: Plan to Publish SharePoint Server and Exchange Server 6082
6.1. Plan to publish SharePoint Server 6083
6.2. Plan to publish Exchange Server 6083
See also 6084

Configure Publishing Applications through Web Application Proxy 6084

Step 1: Configure the Web Application Proxy Infrastructure 6085
1.1. Configure server network settings 6085
1.2. Configure firewalls 6086
1.3. Configure DNS 6086
1.4. Configure Active Directory 6086
Configure Kerberos constrained delegation 6087
1.5. Configure Active Directory Federation Services 6088
See also 6088

Step 2: Install and Configure the Web Application Proxy Server 6088
2.1. Configure CAs and certificates 6089
Configure certificate templates 6089
Configure web application certificates 6089
2.2. Install the Remote Access role 6090
2.3. Configure Web Application Proxy 6091
See also 6092

Step 3: Publish Applications using AD FS Preauthentication 6092
3.1. Publish a Claims-based Application for Web Browser Clients 6093
3.2. Publish an Integrated Windows authenticated-based Application for Web Browser Clients 6095
3.3. Publish an Application that uses MSOFBA 6096
3.4. Publish an Application for a Windows Store App 6096
See also 6097

Step 4: Publish Applications using Client Certificate Preauthentication 6097
4.1. Publish an Application using Client Certificate Preauthentication 6098
See also 6098

Step 5: Publish Applications using Pass-through Preauthentication 6099
5.1. Publish an Application using Pass-Through Preauthentication 6099
See also 6100

Best Practices Analyzer for Web Application Proxy 6101
More information about Web Application Proxy 6101
Topics in this section 6101

Web Application Proxy must be configured before it is used 6102
Issue 6102
Impact 6102
Resolution 6102

Web Application Proxy: The external and backend server URLs are different and URL translation is disabled 6103
Issue 6104
Impact 6104
Resolution 6104

Web Application Proxy: The service is not configured to run automatically 6106
Issue 6106
Impact 6106
Resolution 6106

Web Application Proxy: The AD FS Proxy service is not configured to run automatically 6107
Issue 6107
Impact 6107
Resolution 6107

Web Application Proxy: This server is not included in the ConnectedServersName list 6108
Issue 6108
Impact 6108
Resolution 6109

Web Application Proxy: The ConfigurationChangesPollingIntervalSec value is high 6109
Issue 6110
Impact 6110
Resolution 6110

Web Application Proxy: Application is using an external certificate that is not yet valid 6111
Issue 6111
Impact 6111

Resolution 6111

Web Application Proxy: Application is using an external certificate that is about to expire 6113
Issue 6114
Impact 6114
Resolution 6114

Web Application Proxy: Application is using an external certificate that has no private key 6116
Issue 6117
Impact 6117
Resolution 6117

Web Application Proxy: Application is using an external certificate that has expired 6119
Issue 6120
Impact 6120
Resolution 6120

Web Application Proxy: Application is configured to use an external certificate that is not present on this server 6122
Issue 6122
Impact 6123
Resolution 6123

Web Application Proxy: Some applications are configured to perform backend authentication using Integrated Windows authentication but the server is not joined to a domain 6124
Issue 6124
Impact 6124
Resolution 6125

Web Application Proxy: A cluster of Web Application Proxy servers is deployed and DirectAccess is also installed 6126
Issue 6126
Impact 6126
Resolution 6126

Web Application Proxy: Could not perform Integrated Windows authentication to the backend servers 6127
Issue 6128
Impact 6128
Resolution 6128
Additional references 6129

Web Application Proxy could not publish an application 6129
Issue 6129
Impact 6129
Resolution 6129

Web Application Proxy could not publish an application due to certificate problems 6130
Issue 6130
Impact 6130
Resolution 6130

Web Application Proxy was not able to check for configuration updates 6132
Issue 6132
Impact 6133
Resolution 6133

Web Application Proxy stopped working because it could not retrieve its configuration 6133
Issue 6134
Impact 6134
Resolution 6134

Web Application Proxy: The AD FS Proxy service is stopped 6135
Issue 6135
Impact 6135
Resolution 6135

Web Application Proxy service is stopped 6136
Issue 6136
Impact 6136
Resolution 6137

TCP/IP 6137

Telephony Server and the Telephony API Overview 6138

Virtual Receive-side Scaling in Windows Server 2012 R2 6138

Windows Firewall with Advanced Security Administration with Windows PowerShell 6159
Scope 6159
Audience and user requirements 6160
System requirements 6160
In this guide 6160
Set profile global defaults 6161
Enable Windows Firewall 6161
Control firewall behavior 6161
Deploy basic firewall rules 6162
Create firewall rules 6162
GPO Caching 6163
Modify an existing firewall rule 6163
Delete a firewall rule 6165
Manage remotely 6166
Deploy basic IPsec rule settings 6166
Create IPsec rules 6167
Add custom authentication methods to an IPsec rule 6167
IKEv2 IPsec transport rules 6168
Copy an IPsec rule from one policy to another 6169
Handling Windows PowerShell errors 6169
Monitor 6170
Find the source GPO of a rule 6170
Deploy a basic domain isolation policy 6171
Configure IPsec tunnel mode 6171

Deploy secure firewall rules with IPsec ... 6172
Create a secure firewall rule (allow if secure) ... 6172
Isolate a server by requiring encryption and group membership ... 6173
Create a firewall rule that requires group membership and encryption ... 6174
Endpoint security enforcement ... 6175
Create firewall rules that allow IPsec-protected network traffic (authenticated bypass) ... 6175

Designing a Windows Firewall with Advanced Security Strategy 6211
If you already have firewall or IPsec rules deployed 6212

Gathering the Information You Need 6212

Gathering Information about Your Current Network Infrastructure 6212
Network segmentation 6213
Network address translation (NAT) 6214
Network infrastructure devices 6214
Current network traffic model 6216

Gathering Information about Your Active Directory Deployment 6217

Gathering Information about Your Computers 6218
Automated Discovery 6219
Manual Discovery 6219

Gathering Other Relevant Information 6219
Capacity considerations 6219
Group Policy deployment groups and WMI filters 6220
Different Active Directory trust environments 6220
Creating firewall rules to permit IKE, AH, and ESP traffic 6221
Network load balancing and server clusters 6221
Network inspection technologies 6222

Determining the Trusted State of Your Computers 6223
Trust states 6223
Trusted state 6223
Trustworthy state 6224
Known, untrusted state 6225
Unknown, untrusted state 6226
Capturing upgrade costs for current computers 6226

Planning Your Windows Firewall with Advanced Security Design 6228
Basic firewall design 6228
Algorithm and method support and selection 6228
IPsec performance considerations 6228
Domain isolation design 6229
Server isolation design 6229
Certificate-based authentication design 6229
Documenting your design 6230
Designing groups and GPOs 6230

Planning Settings for a Basic Firewall Policy 6230

Planning Domain Isolation Zones 6232

Exemption List 6232

Isolated Domain 6233
GPO settings for isolated domain members running Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008 R2, or Windows Server 2008 6234

Boundary Zone 6235
GPO settings for boundary zone servers running Windows Server 2012, Windows Server 2008 or Windows Server 2008 R2 6237

Encryption Zone 6238
GPO settings for encryption zone servers running Windows Server 2012, Windows Server 2008 or Windows Server 2008 R2 6238

Planning Server Isolation Zones 6239
Isolated domains and isolated servers 6240
Creating multiple isolated server zones 6240
Creating the GPOs 6240
GPO settings for isolated servers running Windows Server 2012, Windows Server 2008 R2 or Windows Server 2008 6241

Planning Certificate-based Authentication 6242
Deploying certificates 6242
Using Active Directory Certificate Services 6243
Using a commercially purchased certificate for computers running Windows 6243
Using a commercially purchased certificate for computers running a non-Windows operating system 6243
Configuring IPsec to use the certificates 6243

Documenting the Zones 6244

Planning Group Policy Deployment for Your Isolation Zones 6245

Planning Isolation Groups for the Zones 6245

Planning Network Access Groups 6247

Planning the GPOs 6248
General considerations 6248
Woodgrove Bank example GPOs 6249

Firewall GPOs 6250

GPO_DOMISO_Firewall 6250

Firewall settings 6250
Firewall rules 6251

Isolated Domain GPOs 6251

GPO_DOMISO_IsolatedDomain_Clients 6252
General settings 6252
Connection Security Rules 6253

GPO_DOMISO_IsolatedDomain_Servers 6254

Boundary Zone GPOs 6254

GPO_DOMISO_Boundary_WS2008 6255
IPsec settings 6255
Connection security rules 6255
Registry settings 6256
Firewall rules 6256

Encryption Zone GPOs 6256

GPO_DOMISO_Encryption_WS2008 6256
IPsec settings 6257
Connection security rules 6257
Registry settings 6257
Firewall rules 6257

Server Isolation GPOs 6257
GPO_SRVISO_WS2008 6258

Planning GPO Deployment 6258
General considerations 6259
Test your deployed groups and GPOs 6259
Do not enable require mode until deployment is complete 6260
Example Woodgrove Bank deployment plans 6260
GPO_DOMISO_Firewall_2008_Win7-Vista 6260
GPO_DOMISO_IsolatedDomain_Clients_Win7Vista 6261
GPO_DOMISO_IsolatedDomain_Servers_WS2008 6261
GPO_DOMISO_Boundary_WS2008 6261
GPO_DOMISO_Encryption_WS2008 6261

Checklist: Implementing a Certificate-based Isolation Policy Design ... 6295

Procedures Used in This Guide ... 6296

Add Production Computers to the Membership Group for a Zone ... 6298

Add Test Computers to the Membership Group for a Zone ... 6299

Assign Security Group Filters to the GPO 6300

Change Rules from Request to Require Mode 6302

Configure Authentication Methods on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6303

Configure Data Protection (Quick Mode) Settings on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6306

Configure Group Policy to Autoenroll and Deploy Certificates 6308

Configure Key Exchange (Main Mode) Settings on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6308

Configure the Rules to Require Encryption on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6310

Configure the Windows Firewall Log 6311

Configure the Workstation Authentication Certificate Template 6312

Configure Windows Firewall to Suppress Notifications When a Program Is Blocked 6313

Confirm That Certificates Are Deployed Correctly 6315

Copy a GPO to Create a New GPO 6315

Create a Group Account in Active Directory 6316

Create a Group Policy Object 6317

Create an Authentication Exemption List Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6318

Create an Authentication Request Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6319

Create an Inbound ICMP Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6322

Create an Inbound Port Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6324

Create an Inbound Program or Service Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6326

Create an Outbound Port Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008 or Windows Server 2008 R2 6328

Create an Outbound Program or Service Rule on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008 or Windows Server 2008 R2 6329

Create Inbound Rules to Support RPC on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6331

Create WMI Filters for the GPO 6333

Enable Predefined Inbound Rules on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6335

Enable Predefined Outbound Rules on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6336

Exempt ICMP from Authentication on Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, and Windows Server 2008 R2 6337

Install Active Directory Certificate Services 6338

Link the GPO to the Domain 6339

Modify GPO Filters to Apply to a Different Zone or Version of Windows 6340

Open the Group Policy Management Console to IP Security Policies 6342

Open the Group Policy Management Console to Windows Firewall 6342

Open the Group Policy Management Console to Windows Firewall with Advanced Security 6342

Open Windows Firewall with Advanced Security 6343
- Opening Windows Firewall with Advanced Security 6343

Restrict Server Access to Members of a Group Only 6344

Start a Command Prompt as an Administrator 6345

Turn on Windows Firewall and Configure Default Behavior 6346

Verify That Network Traffic Is Authenticated 6346
- For computers running Windows 8, Windows 7, Windows Vista, Windows Server 2012, Windows Server 2008, or Windows Server 2008 R2 6347

Additional Resources 6348

Migrate Print and Document Services to Windows Server 2012 ... 6466
Overview ... 6466
About this guide ... 6468
Target audience ... 6468
What this guide does not provide ... 6468
Supported migration scenarios ... 6468
Supported operating systems ... 6468
Supported role configurations ... 6470
Supported role services and features ... 6470
Migrating from x86-based to x64-based v3 printer drivers ... 6470
Unsupported scenarios ... 6471
Print and Document Services migration overview ... 6471
Migrate print servers (overview) ... 6472
Impact of migration ... 6472
Impact of migration on the source server ... 6472
Impact of migration on other computers in the enterprise ... 6472
Permissions required to complete migration ... 6473
Permissions required to complete migration on other computers in the enterprise ... 6473
Estimated duration ... 6473
See Also ... 6473

Preparing to Migrate ... 6474
Access the migration tools ... 6474
To access the Printer Migration Wizard ... 6474
To access the Printbrm.exe command-line tool ... 6475
Prepare the destination server ... 6475
Hardware requirements for the destination server ... 6475

Software requirements for the destination server ... 6475
Installing the Print and Document Services role on the destination server ... 6476
Preparing for cross-architecture migrations ... 6476
Preparing for additional scenarios ... 6476
Prepare the source server ... 6477
See Also ... 6478

Migrating the Print and Document Services Role ... 6478
Back up the source server ... 6478
Cross-architecture migrations ... 6480
Restoration ... 6480
See Also ... 6481

Verifying the Migration ... 6482
Verify the migration ... 6482
To verify destination server configuration ... 6482
Rename the destination server to the name of the source server ... 6483
To verify configuration of other computers in the enterprise ... 6483
Print a test job from a client with an existing connection ... 6484
See Also ... 6484

Post-Migration Tasks ... 6484
Post-migration ... 6484
Success ... 6484
Retire the source server ... 6484
Failure ... 6485
Restoring the role in the event of migration failure ... 6485
Rollback requirements ... 6485
Estimated time to complete rollback ... 6485
Roll back migration on the source server ... 6486
Roll back migration on the destination server ... 6486
Troubleshooting ... 6486
Log file locations ... 6486
Migrating cross-platform driver language monitors ... 6486
Mitigating a failure in the Print Spooler service ... 6486
Additional references ... 6487
See Also ... 6487

Appendix A - Printbrm.exe Command-Line Tool Details ... 6487
Printbrm.exe command-line tool syntax ... 6487
Printbrm enhancements ... 6488
Printbrm usage scenarios ... 6489
Using the configuration file ... 6489
Selectively restoring your printers ... 6490

Moving printers to a different domain ... 6490
See Also ... 6491

Appendix B - Additional Destination Server Scenarios ... 6491
If your server hosts Line Printer Remote (LPR) printers ... 6491
If your server offers Internet Printing Protocol (IPP) printer connections ... 6492
If your server hosts Web Services on Devices (WSD) printers ... 6492
If your print server is a highly available virtual machine ... 6492
If your server hosts local bus printers (LPT and USB) ... 6492
If your server hosts plug and play printers ... 6492
See Also ... 6493

Appendix C - Printbrm Event IDs ... 6493
Printbrm Event IDs ... 6493

Test Lab Guide: Virtual Desktop Infrastructure Quick Start ... 6549
In this guide ... 6549
Test lab overview ... 6550
Hardware and software requirements ... 6551
Steps for configuring the test lab ... 6551
Step 1: Complete the base configuration test lab ... 6552
Step 2: Configure APP1 ... 6552
Step 3: Test Remote Desktop Services connectivity ... 6552
Step 4: Take a snapshot of the configuration ... 6553
Additional Resources ... 6553

Test Lab Guide: Virtual Desktop Infrastructure Standard Deployment 6554
In this guide 6554
Test lab overview 6554
Hardware and software requirements 6555
Steps for configuring the test lab 6556
Step 1: Complete the base configuration test lab 6556
Step 2: Install and Configure RDVH1 6556
Install the operating system on RDVH1 6557
Configure TCP/IP properties 6557
Join RDVH1 to the CORP domain 6558
Step 3: Install and Configure RDWA1 6558
Install the operating system on RDWA1 6558
Configure TCP/IP properties 6559
Join RDWA1 to the CORP domain 6560
Step 4: Install and Configure RDCB1 6560
Install the operating system on RDCB1 6560
Configure TCP/IP properties 6561
Join RDCB1 to the CORP domain 6562
Step 5: Deploy the Virtual Desktop Infrastructure standard deployment 6562
Step 6: Test the VDI standard deployment connectivity 6563
Step 7: Take a snapshot of the configuration 6564
Additional Resources 6564

Test Lab Guide: Managed Pooled Virtual Desktop Collections 6564
In this guide 6565
Test lab overview 6565
Hardware and software requirements 6566
Steps for configuring the test lab 6567
Step 1: Complete the VDI standard deployment test lab 6567
Step 2: Configure RDCB1 6567
Step 3: Configure RDVH1 6568
Step 4: Create the managed pooled virtual desktop collection 6569
Step 5: Test Remote Desktop Services connectivity 6570
Step 6: Take a snapshot of the configuration 6570
Additional Resources 6571

Test Lab Guide: Unmanaged Pooled Virtual Desktop Collections 6571
In this guide 6571
Test lab overview 6572
Hardware and software requirements 6573
Steps for configuring the test lab 6573
Step 1: Complete the VDI standard deployment test lab 6574
Step 2: Configure RDCB1 6574
Step 3: Create the unmanaged pooled virtual desktop collection 6575

Step 4: Test Remote Desktop Services connectivity 6576
Step 5: Take a snapshot of the configuration 6576
Additional Resources 6577

Test Lab Guide: Remote Desktop Services Session Virtualization Quick Start 6577
Introduction 6577
In this guide 6578
Test lab overview 6578
Hardware and software requirements 6579
Steps for configuring the test lab 6579
Step 1: Complete the Base Configuration Test Lab 6580
Step 2: Configure APP1 6580
Deploy the Session Virtualization Quick Start 6580
Step 3: Test Remote Desktop Service Connectivity 6581
Connect to the Session Collection 6581
Step 4: Snapshot the Configuration 6581
Additional Resources 6582

Test Lab Guide: Remote Desktop Services Session Virtualization Standard Deployment 6582
In this guide 6583
Test lab overview 6583
Hardware and software requirements 6584
Steps for configuring the test lab 6584
Step 1: Complete the base configuration test lab 6585
Step 2: Install and Configure RDSH1 6585
Install the operating system on RDSH1 6585
Configure TCP/IP properties 6586
Join RDSH1 to the CORP domain 6587
Step 3: Install and Configure RDWA1 6587
Install the operating system on RDWA1 6587
Configure TCP/IP properties 6588
Join RDWA1 to the CORP domain 6589
Step 4: Install and Configure RDCB1 6589
Install the operating system on RDCB1 6589
Configure TCP/IP properties 6590
Join RDCB1 to the CORP domain 6591
Step 5: Deploy Session Virtualization Standard 6591
Add RDSH1, RDWA1, and RDCB1 to the server pool 6591
Deploy the Session Virtualization Standard deployment 6592
Step 6: Create Session Collection 6592
Create a session collection 6593
Step 7: Test Remote Desktop Services Connectivity 6593
Connect to the session collection 6593
Step 8: Snapshot the Configuration 6594

Additional Resources 6594

Test Lab Guide: Remote Desktop Services Publishing 6595
Introduction 6595
In this guide 6595
Test lab overview 6595
Hardware and software requirements 6596
Steps for configuring the test lab 6597
Step 1: Complete the Demonstrate Remote Desktop Services Session Virtualization Standard Deployment Test Lab 6597
Step 2: Publish a RemoteApp Program 6598
Publish a RemoteApp program 6598
Step 3: Enable File Type Association on a RemoteApp Program 6598
Enable the default connection URL using Group Policy 6598
Configure the File Type Association 6599
Step 4: Configure DNS Feed Lookup for RemoteApp and Desktop Connections 6599
Configure DNS Feed Lookup for RemoteApp and Desktop Connections. 6599
Step 5: Test Published RemoteApp Program using RD Web Access 6600
Test Published RemoteApp Program using RD Web Access 6600
Step 6: Snapshot the Configuration 6600

BitLocker Frequently Asked Questions (FAQ) ... 6921
Overview and requirements ... 6924
What is BitLocker? How does it work? ... 6924
Does BitLocker support multifactor authentication? ... 6925
What are the BitLocker hardware and software requirements? ... 6925
Why are two partitions required? Why does the system drive have to be so large? ... 6927
Which Trusted Platform Modules (TPMs) does BitLocker support? ... 6928
How can I tell if a TPM is on my computer? ... 6928
Can I use BitLocker on an operating system drive without a TPM? ... 6928
How do I obtain BIOS support for the TPM on my computer? ... 6929
What credentials are required to use BitLocker? ... 6929
What is the recommended boot order for computers that are going to be BitLocker-protected? ... 6929
Upgrading ... 6930

Can I upgrade my Windows 7–based computer to Windows 8 with BitLocker enabled? .. 6930
What is the difference between suspending and decrypting BitLocker? 6930
Do I have to decrypt my BitLocker-protected drive to download and install system updates and upgrades? 6930
Deployment and administration 6931
Can BitLocker deployment be automated in an enterprise environment? 6931
Can BitLocker encrypt more than just the operating system drive? 6931
Is there a noticeable performance impact when BitLocker is enabled on a Windows 8–based computer? 6931
Approximately how long will initial encryption take when BitLocker is turned on? 6932
What happens if the computer is turned off during encryption or decryption? 6932
Does BitLocker encrypt and decrypt the entire drive all at once when reading and writing data? 6932
How can I prevent users on a network from storing data on an unencrypted drive? 6932
What system changes would cause the integrity check on my operating system drive to fail? 6933
What causes BitLocker to start into recovery mode when attempting to start the operating system drive? 6933
Can I swap hard disks on the same computer if BitLocker is enabled on the operating system drive? 6935
Can I access my BitLocker-protected drive if I insert the hard disk into a different computer? 6935
Why is "Turn BitLocker on" not available when I right-click a drive? 6936
What type of disk configurations are supported by BitLocker? 6936
What if my disk configuration is not listed? 6937
Key management 6937
What is the difference between a TPM owner password, recovery password, recovery key, password, PIN, enhanced PIN, and startup key? 6937
How can the recovery password and recovery key be stored? 6940
Is it possible to add an additional method of authentication without decrypting the drive if I only have the TPM authentication method enabled? 6940
If I lose my recovery information, will the BitLocker-protected data be unrecoverable? 6940
Can the USB flash drive that is used as the startup key also be used to store the recovery key? 6940
Can I save the startup key on multiple USB flash drives? 6941
Can I save multiple (different) startup keys on the same USB flash drive? 6941
Can I generate multiple (different) startup keys for the same computer? 6941
Can I generate multiple PIN combinations? 6941
What encryption keys are used in BitLocker? How do they work together? 6941
Where are the encryption keys stored? 6941
Why do I have to use the function keys to enter the PIN or the 48-character recovery password? 6942

How does BitLocker help prevent an attacker from discovering the PIN that unlocks my operating system drive? ... 6942
How can I determine the manufacturer of my TPM? ... 6942
How can I evaluate a TPM's dictionary attack mitigation mechanism? ... 6943
Can PIN length and complexity be managed with Group Policy? ... 6943
BitLocker To Go ... 6943
What is BitLocker To Go? ... 6943
How can I authenticate or unlock my removable data drive? ... 6943
What happens if I try to open a BitLocker-protected, NTFS-formatted removable drive by using a computer running Windows XP or Windows Vista? ... 6943
Is there a way to ensure the BitLocker To Go Reader is not installed on FAT-formatted drives? ... 6944
Can I save files to my BitLocker-protected removable drive when I am using Windows XP or Windows Vista? ... 6944
Can I download a copy of the BitLocker To Go Reader? ... 6944
Why am I unable to access my removable drive on computers running Windows XP or Windows Vista when using the BitLocker To Go Reader? ... 6944
Active Directory Domain Services (AD DS) ... 6945
Does BitLocker require a schema extension to store recovery information in AD DS? ... 6945
What type of information is stored in AD DS? ... 6945
Does BitLocker encrypt recovery information as it is sent to AD DS? ... 6946
Is the BitLocker recovery information stored in plaintext in AD DS? ... 6946
What if BitLocker is enabled on a computer before the computer has joined the domain? 6947
Is there an event log entry recorded on the client computer to indicate the success or failure of the Active Directory backup? ... 6947
If I change the BitLocker recovery password on my computer and store the new password in AD DS, will AD DS overwrite the old password? ... 6947
What happens if the backup initially fails? Will BitLocker retry the backup? ... 6948
Security ... 6948
What form of encryption does BitLocker use? Is it configurable? ... 6948
What is the best practice for using BitLocker on an operating system drive? ... 6948
What are the implications of using the sleep or hibernate power management options? ... 6949
What are the advantages of a TPM? ... 6949
Is Microsoft pursuing any security certification for BitLocker? ... 6949
BitLocker Network Unlock ... 6949
What is BitLocker Network Unlock? ... 6949
What is required to use BitLocker Network Unlock? ... 6950
How is BitLocker Network Unlock different from automatic unlock? ... 6950
How do I unlock my computer when not connected to the network? ... 6950
Other questions ... 6950
Can I use EFS with BitLocker? ... 6950
Can I run a kernel debugger with BitLocker? ... 6951
How does BitLocker handle memory dumps? ... 6951

Can BitLocker support smart cards for pre-boot authentication? 6951
Can I use a non-Microsoft TPM driver? 6951
Can other tools that manage or modify the master boot record work with BitLocker? 6951
Why is the system check failing when I am encrypting my operating system drive? 6951
What can I do if the recovery key on my USB flash drive cannot be read? 6952
Why am I unable to save my recovery key to my USB flash drive? 6952
Why am I unable to automatically unlock my drive? 6952
Can I use BitLocker in Safe Mode? 6952
How do I "lock" a data drive? 6953
Can I use BitLocker with the Volume Shadow Copy Service? 6953
Does BitLocker support virtual hard disks (VHDs)? 6953

Encryption keys and authentication 6969

TPM hardware configurations 6972
TPM states of existence 6972
Endorsement keys 6973
Non-TPM hardware configurations 6974
Disk configuration considerations 6974
BitLocker provisioning 6975
Used Disk Space Only encryption 6975
Active Directory Domain Services considerations 6976
FIPS support for recovery password protector 6978
More information 6979

BitLocker Group Policy Settings 6979
Overview 6980
BitLocker Group Policy settings 6980
Allow network unlock at startup 6982
Require additional authentication at startup 6983
Allow enhanced PINs for startup 6984
Configure minimum PIN length for startup 6985
Disallow standard users from changing the PIN or password 6986
Configure use of passwords for operating system drives 6987
Require additional authentication at startup (Windows Server 2008 and Windows Vista). 6988
Configure use of smart cards on fixed data drives 6990
Configure use of passwords on fixed data drives 6991
Configure use of smart cards on removable data drives 6992
Configure use of passwords on removable data drives 6993
Validate smart card certificate usage rule compliance 6995
Enable use of BitLocker authentication requiring preboot keyboard input on slates 6996
Deny write access to fixed drives not protected by BitLocker 6997
Deny write access to removable drives not protected by BitLocker 6998
Control use of BitLocker on removable drives 6999
Choose drive encryption method and cipher strength 7000
Configure use of hardware-based encryption for fixed data drives 7001
Configure use of hardware-based encryption for operating system drives 7002
Configure use of hardware-based encryption for removable data drives 7003
Enforce drive encryption type on fixed data drives 7005
Enforce drive encryption type on operating system drives 7006
Enforce drive encryption type on removable data drives 7007
Choose how BitLocker-protected operating system drives can be recovered 7008
Choose how users can recover BitLocker-protected drives (Windows Server 2008 and Windows Vista) 7009
Store BitLocker recovery information in Active Directory Domain Services (Windows Server 2008 and Windows Vista) 7010
Choose default folder for recovery password 7012

Choose how BitLocker-protected fixed drives can be recovered 7013
Choose how BitLocker-protected removable drives can be recovered 7014
Allow Secure Boot for integrity validation 7016
Provide the unique identifiers for your organization 7017
Prevent memory overwrite on restart 7018
Configure TPM platform validation profile for BIOS-based firmware configurations 7019
Configure TPM platform validation profile (Windows Vista, Windows Server 2008, Windows 7, Windows Server 2008 R2) 7021
Configure TPM platform validation profile for native UEFI firmware configurations 7022
Reset platform validation data after BitLocker recovery 7024
Use enhanced Boot Configuration Data validation profile 7025
Allow access to BitLocker-protected fixed data drives from earlier versions of Windows 7026
Allow access to BitLocker-protected removable data drives from earlier versions of Windows 7027
FIPS setting 7029
Power management Group Policy settings: Sleep and Hibernate 7029
About the Platform Configuration Register (PCR) 7030

Advanced Security Auditing FAQ 7189
What is Windows security auditing and why might I want to use it? 7190
What is the difference between audit policies located in Local Policies\Audit Policy and audit policies located in Advanced Audit Policy Configuration? 7191
What is the interaction between basic audit policy settings and advanced audit policy settings? 7192
How are audit settings merged by Group Policy? 7193
What is the difference between an object DACL and an object SACL? 7194
Why are audit policies applied on a per-computer basis rather than per user? 7194
What are the differences in auditing functionality between versions of Windows? 7195
Can I use advanced audit policies from a domain controller running Windows Server 2003 or Windows 2000 Server? 7195
What is the difference between success and failure events? Is something wrong if I get a failure audit? 7195
How can I set an audit policy that affects all objects on a computer? 7195

How do I figure out why someone was able to access a resource? 7196
How do I know when changes are made to access control settings, by whom, and what the changes were? 7196
How can I roll back security audit policies from the advanced audit policy to the basic audit policy? 7197
How can I monitor if changes are made to audit policy settings? 7197
How can I minimize the number of events that are generated? 7197
What are the best tools to model and manage audit policies? 7198
Where can I find information about all the possible events that I might receive? 7198
Where can I find more detailed information? 7198

Advanced Security Auditing Walkthrough 7199
About this guide 7199
Deploying advanced audit policy settings in a test environment 7200
Steps for deploying advanced audit policies in a test environment 7202
Step 1: Set up the infrastructure 7202
Configure the domain controller (CONTOSO-DC) 7203
Configure the member server (CONTOSO-SRV) running Windows Server 2008 R2 7204
Configure the client computer (CONTOSO-CLNT) 7206
Step 2: Create and verify an advanced audit policy 7208
Step 3: Create and verify an audit policy that provides the reason for object access 7210
Step 4: Create and verify a global object access policy 7212
Step 5: Create and verify additional advanced audit policies 7213
Managing per-user auditing 7214
Optional section: Roll back security audit policy from advanced audit policy to basic audit policy 7215

Which Editions of Windows Support Advanced Audit Policy Configuration 7215
Are there any special considerations? 7216

Software Restriction Policies Technical Overview ... 7783
Introduction ... 7783
Procedures ... 7784
Software restriction policy usage scenarios ... 7784
Differences and changes in functionality ... 7785
System requirements ... 7788
Software restriction policies components and architecture ... 7788
Best practices ... 7789
Do not modify the default domain policy. ... 7789
Create a separate Group Policy Object for software restriction policies. ... 7789
If you experience problems with applied policy settings, restart Windows in Safe Mode. ... 7789
Use caution when defining a default setting of Disallowed. ... 7790
For best security, use access control lists in conjunction with software restriction policies. ... 7790
Test new policy settings thoroughly in test environments before applying the policy settings to your domain. ... 7790
Filter user policy settings based on membership in security groups. ... 7790
Do not link to a GPO in another domain or site. ... 7790
Additional resources ... 7791

Administer Software Restriction Policies 7791
Introduction 7791
To open Software Restriction Policies 7792
For your local computer 7792
For a domain, site, or organizational unit, and you are on a member server or on a workstation that is joined to a domain 7792
For a domain or organizational unit, and you are on a domain controller or on a workstation that has the Remote Server Administration Tools installed 7793
For a site, and you are on a domain controller or on a workstation that has the Remote Server Administration Tools installed 7793
To create new software restriction policies 7794
To add or delete a designated file type 7794
To prevent software restriction policies from applying to local administrators 7795
To change the default security level of software restriction policies 7795
To apply software restriction policies to DLLs 7796

Determine Allow/Deny List and Application Inventory for Software Restriction Policies 7796
Introduction 7797
What default rule to choose: Allow or Deny 7797
Create an inventory of your applications for the Allow list 7797

Work with Software Restriction Policies Rules 7798
Introduction 7798
Working with certificate rules 7799
Enabling certificate rules 7800
Set trusted publisher options 7802
Working with hash rules 7803
Working with Internet Zone rules 7804
Working with path rules 7805

Use Software Restriction Policies to Help Protect Your Computer Against an Email Virus 7806
Introduction 7806

Troubleshoot Software Restriction Policies 7807
Introduction 7807
Windows cannot open a program 7808
Modified software restriction policies are not taking effect 7808
After adding a rule through SRP, you cannot log on to your computer 7809
A new policy setting is not applying to a specific file name extension 7809
A default rule is not restricting as expected 7809
Unable to discover which restrictions are applied 7809

TLS/SSL (Schannel SSP) Overview 7810
TLS/SSL (Schannel) description 7810
Practical applications 7810

New and changed functionality 7811
Deprecated functionality 7811
Software requirements 7811
Server Manager information 7811
See also 7812

What's New in TLS/SSL (Schannel SSP) 7812
TLS/SSL (Schannel SSP) description 7812
New and changed functionality in Windows Server 2012 R2 7813
TLS session resumption 7813
Application Protocol Negotiation 7813
New and changed functionality in Windows Server 2012 7814
Management of trusted issuers for client authentication 7814
TLS support for Server Name Indicator (SNI) Extensions 7816
Datagram Transport Layer Security (DTLS) 7816
Deprecated functionality 7817
See also 7817

Trusted Platform Module Technology Overview 7817
Feature description 7818
Practical applications 7818
New and changed functionality 7819
Automated provisioning and management of the TPM 7819
Measured Boot with support for attestation 7820
TPM-based Virtual Smart Card 7820
TPM-based certificate storage 7820
TPM Owner Authorization Value 7820
TPM Cmdlets 7821
Supported versions 7821
Additional Resources 7822

Schema Extensions for Windows Server 2008 R2 to support AD DS backup of TPM information from Windows 8 clients 7822
Why a schema extension is needed 7822

New and changed functionality ... 7849
Removed or deprecated functionality ... 7850
Software requirements ... 7850
Server Manager information ... 7850

Windows Server 2012 R2 Software Inventory Logging Overview ... 7850
Feature description ... 7851
Practical applications ... 7851
Software requirements ... 7852
See Also ... 7852

Manage Software Inventory Logging in Windows Server 2012 R2 ... 7852
Starting and Stopping Software Inventory Logging ... 7853
Displaying Software Inventory Logging data ... 7854
Forwarding Software Inventory Logging data ... 7856
Deleting data logged by Software Inventory Logging ... 7857
Backing up and restoring data logged by Software Inventory Logging ... 7857
Configuring certificates for Software Inventory Logging ... 7858
Enabling Software Inventory using unattended installation ... 7859
Creating a master VHD image to deploy Software Inventory Logging to servers in an enterprise ... 7859
See also ... 7860

Telemetry Overview ... 7860
Feature description ... 7860
See also ... 7860

Deploy Windows Feedback Forwarder ... 7861
Participate in the Customer Experience Improvement Program ... 7861
Participate in Windows Error Reporting ... 7862
Configure all servers to participate in CEIP and WER ... 7864
Install Windows Feedback Forwarder ... 7864
Install Windows Feedback Forwarder by using Add Roles and Features Wizard ... 7865
Install Windows Feedback Forwarder on a Server Core installation ... 7867
Configure Windows Feedback Forwarder ... 7867

What's New in Telemetry ... 7868
Feature description ... 7868
New and changed functionality ... 7869
Windows Feedback Forwarder ... 7870
Windows Automatic Feedback ... 7870
See also ... 7870

User Access Logging Overview ... 7870
Feature description ... 7871
Practical applications ... 7871
Important functionality ... 7872
Data logged with UAL ... 7873
Software requirements ... 7874
See also ... 7874

Manage User Access Logging ... 7875
Disabling and enabling the UAL service ... 7875
Collecting UAL data ... 7877
Deleting data logged by UAL ... 7879
Managing UAL in high volume environments ... 7879
Recovering from a corrupt state ... 7880
Enable Work Folders usage license tracking ... 7880
See also ... 7880

Volume Activation Overview ... 7881
Volume activation description ... 7881
How does volume activation work? ... 7882
Practical applications ... 7884
What is activation? ... 7884
What are my activation options? ... 7884
What happens if systems are not activated? ... 7885
When should I use volume activation? ... 7885
System requirements ... 7886
Additional information ... 7886

Test Lab Guide: Demonstrate Volume Activation Services ... 7887
Setting up Volume Activation Services in a test environment ... 7887
Step 1: Set up the base test lab infrastructure ... 7887
Step 2: Install the Volume Activation Services server role ... 7888
Step 3: Configure Active Directory-based Activation ... 7889
Step 4: Verify that Active Directory-based Activation works ... 7890
Step 5: Configure Key Management Services ... 7890
Step 6: Verify that KMS volume activation works ... 7891
Additional information ... 7892

Plan for Volume Activation 7892

Step 1: Review and Select Activation Methods 7892
1.1 Plan for Active Directory-based Activation 7893
Using Active Directory-based Activation in mixed Windows activation environments 7894
Utilizing Active Directory-based Activation failover capability 7894
1.2 Plan for Key Management Services activation 7895
Addressing KMS operational requirements 7896
Addressing KMS functional requirements 7897
1.3 Plan for Multiple Activation Key activation 7897
See also 7898

Step 2: Evaluate Client Connectivity 7898
Activation scenarios 7899
2.1. Identify scenario requirements for the central network 7900
2.2. Identify scenario requirements for the branch office network 7901
2.3. Identify high-security zone scenario requirements 7902
2.4. Identify disconnected computer scenario requirements 7903
2.5 Identify test and development lab requirements 7903
See also 7904

Step 3: Determine Activation Method and Product License Requirements 7904
See also 7905

Step 4: Determine Monitoring and Reporting Needs 7906
4.1 Managing Active Directory-based Activation objects 7906
4.2 Managing Activation with System Center Configuration Manager 7907
4.3 Managing Activation by Using Event Logs 7907
4.4 Managing Activation by Using the Volume Activation Management Tool 7908
See also 7908

Appendix A: KMS Client Setup Keys 7908
Windows Server 2012 R2 and Windows 8.1 Client Setup Keys 7908
Windows Server 2012 and Windows 8 Client Setup Keys 7909
Windows 7 and Windows Server 2008 R2 7909
Windows Vista and Windows Server 2008 7910

Deploy Volume Activation 7911
Methods of volume activation 7911

Deploy Active-Directory-based Activation 7911
Using Active Directory-based activation 7912
Managing the activation object 7912
Appendix A: Administration delegation script 7913

Deploy KMS Activation 7916

Configuring KMS hosts 7916
Configuring DNS 7916
Change the Default DNS Permissions for SRV Records 7916
Publish to Multiple DNS Domains 7917
Manually Create SRV Records in DNS 7918
Installing KMS hosts 7919
Configuring KMS clients 7920

Deploy MAK Activation 7921
Installing a MAK During Operating System Installation 7921

Volume Activation Technical Reference 7923
Technical Reference for Volume Activation 7923
See also 7924

Hosting-Friendly Web Server Platform (IIS): Scenario Overview 7970
Scenario Description 7970
Web Server Scenarios 7971
Practical Applications 7972
See Also 7972

Build a Static Website on IIS 7973
Prerequisites 7973
Step 1: Install the IIS Web Server 7973
Step 2: Add a Website 7975
Step 3: Configure Anonymous Authentication 7976
Step 4: Configure the Default Documents 7977
Step 5: Configure Static Content Compression 7978
Next Steps 7979
See also 7979

Configure Logging in IIS 7979
Prerequisites 7979
Configure Logging at the Site Level 7980
Configure Per-site Logging at the Server Level 7981
Configure Per-server Logging at the Server Level 7982
Select W3C Fields to Log 7982
Configure Log File Rollover Options 7983
See Also 7984

Configure Request Filtering in IIS 7984
Prerequisites 7985
General Request Filter Settings 7985

File Name Extensions 7987
Filtering Rules 7988
Hidden Segments 7988
URL Filtering 7989
HTTP Verbs 7989
Header Size Limits 7990
Query Strings 7991
Request Filter Logging 7991
See Also 7992

Build a Classic ASP Website on IIS 7992
Prerequisites 7992
Step 1: Install the IIS Web Server 7993
Step 2: Add a Classic ASP Website 7994
Step 3: Edit ASP Application Settings 7996
Next Steps 8002
See also 8002

Build an ASP.NET Website on IIS 8003
Scenario Description 8003
In This Scenario 8003
Practical Applications 8004
Software Requirements 8004
See Also 8004

Plan an ASP.NET Website on IIS 8004

Step 1: Plan IIS Web Server and ASP.NET Modules Installation 8005
1.1. Plan to Install IIS and ASP.NET Modules 8005
1.2. Plan to Add the ASP.NET Application 8005
See Also 8006

Step 2: Plan ASP.NET Settings 8006
2.1. Session State Settings 8006
Store session state in process 8007
Store session state by using state server 8008
Store session state by using SQL server 8008
Cookie mode for session state 8009
2.2. Pages and Controls Settings 8010
2.3. Application Settings 8011
2.4. .NET Compilation Settings 8011
2.5. .NET Globalization Settings 8012

Step 3: Plan Data Source Settings 8012
3.1. Data source connection strings 8012

3.2. ASP.NET providers ... 8013
3.3. .NET profiles ... 8014
3.4. .NET roles ... 8014
3.5. .NET users ... 8014

Step 4: Plan Application Security ... 8015
4.1. Isolate Web Applications ... 8015
4.2. .NET Trust Levels ... 8016
4.3. .NET Authentication ... 8016
ASP.NET Forms Authentication ... 8017
Forms authentication basics ... 8017
Authentication cookies ... 8018
ASP.NET Impersonation Authentication ... 8020
4.4. Machine Key Settings ... 8020
4.5. TLS/SSL Communication ... 8021

Migrate Windows Server Update Services to Windows Server 2012 8440

Step 1: Plan for WSUS Migration 8440
1.1. Know supported operating systems 8441

1.2. Review supported migration scenarios 8441
1.3. Review migration scenarios that are not supported 8442
See also 8442

Step 2: Prepare to Migrate WSUS 8442
2.1. Prepare before you start the migration 8443
2.2. Prepare the destination server 8443
2.3. Prepare the source server 8444
See also 8444

Step 3: Migrate WSUS 8445
3.1. Migrate WSUS update binaries 8445
3.2. Migrate WSUS security groups 8446
3.3. Back up the WSUS database 8447
3.4. Change the WSUS server identity 8451
3.5. Apply security settings 8451
Point the downstream servers to the new WSUS server 8452
Point the WSUS clients to the new WSUS server 8452
3.6. Review additional considerations 8453
See also 8453

Step 4: Verify the WSUS Migration 8454
4.1. Verify the destination server configuration 8454
4.2. Verify client computer functionality 8454
See also 8454

Deploy Windows Server Update Services in Your Organization 8455

Step 1: Prepare for Your WSUS Deployment 8455
1.1. Review considerations and system requirements 8456
WSUS database requirements 8457
1.2. Choose a WSUS deployment scenario 8458
Simple WSUS deployment 8458
Multiple WSUS servers 8459
Disconnected WSUS server 8460
WSUS server hierarchies 8461
Autonomous mode 8461
Replica mode 8462
Branch offices 8463
Network Load Balancing 8464
WSUS deployment with roaming client computers 8464
1.3. Choose a WSUS storage strategy 8465
WSUS database 8465
WSUS with Windows Internal Database 8466
WSUS with SQL Server 8466

WSUS update storage ... 8467
Local WSUS server storage ... 8467
Remote storage on Microsoft Update servers ... 8467
1.4. Choose WSUS update languages ... 8468
1.5. Plan WSUS computer groups ... 8470
Conflict Resolution ... 8471
Priority ... 8471
Priority of Install and Uninstall ... 8472
Priority of Deadlines ... 8472
1.6. Plan WSUS performance considerations ... 8472
Network setup ... 8472
Deferred download ... 8473
Filters ... 8473
Installation ... 8473
Large update deployment ... 8475
Background Intelligent Transfer Service ... 8475
1.7. Plan Automatic Updates settings ... 8475
See also ... 8476

Step 2: Install the WSUS Server Role ... 8476
See also ... 8477

Step 3: Configure WSUS ... 8478
3.1. Configure network connections ... 8478
3.1.1. Connection from the WSUS server to the Internet ... 8479
3.1.2. Connection between WSUS servers ... 8479
3.1.3. Connection between clients (Windows Update Agent) and WSUS servers ... 8480
Configure the proxy server ... 8480
3.2. Configure WSUS by using the WSUS Configuration Wizard ... 8481
3.3. Configure computer groups ... 8483
3.4. Configure client updates ... 8484
Configure Automatic Updates in Group Policy ... 8485
3.5. Secure WSUS with the Secure Sockets Layer Protocol ... 8487
Limitations of WSUS SSL deployments ... 8487
Configure SSL on the WSUS server ... 8487
Configure SSL on client computers ... 8488
Configure SSL for downstream WSUS servers ... 8489
Additional SSL resources ... 8489
3.6. Complete IIS Configuration ... 8490
3.6. Configure a Signing Certificate ... 8490
See also ... 8490

Step 4: Approve and Deploy WSUS Updates ... 8490
4.1. Approve and deploy WSUS updates ... 8491

4.2. Configure auto-approval rules ... 8491
4.3. Review installed updates with WSUS Reports ... 8492
See also ... 8492

Windows Server 2012 R2 and Windows Server 2012

Welcome to the Windows Server 2012 R2 and Windows Server 2012 Technical Library.

This library provides the core content that IT pros need to evaluate, plan, deploy, manage, troubleshoot, and support servers running the Windows Server 2012 R2 and Windows Server 2012 operating systems. To find the information you need, browse the content listed below, or use our search feature. If you need help with using Windows at home, see Windows Help and How-To.

- What's New in Windows Server 2012 R2
  The content in this section describes what's new and changed in Windows Server 2012 R2. This content focuses on changes that will potentially have the greatest impact on your use of this release.
- What's New in Windows Server 2012
  This section describes what's new and changed in Windows Server 2012. This content focuses on changes that will potentially have the greatest impact on your use of this release.
- Technical Scenarios for Windows Server 2012 R2 and Windows Server 2012
  These technical scenarios provide guidance that addresses an area of interest or particularly compelling capability enabled by Windows Server 2012 R2 and Windows Server 2012, such as virtualization and Dynamic Access Control.
- Install and Deploy Windows Server 2012 R2 and Windows Server 2012
  This section provides information about how to migrate to, install, and deploy Windows Server 2012 R2 and Windows Server 2012.
- Migrate Roles and Features to Windows Server
  Migration documentation and tools ease the process of migrating server roles, features, operating system settings, and data from an existing server that is running Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or Windows Server 2003 to a computer that is running Windows Server 2012.
- Secure Windows Server 2012 R2 and Windows Server 2012
  This section provides the security products and assessment tools needed to help secure servers running Windows Server 2012 R2 or Windows Server 2012.
- Manage Privacy
  This section offers not only guidance about managing privacy-related settings in Windows Server 2012, but also links that can be useful to administrators and others concerned about privacy.
- Support Windows Server 2012 R2 and Windows Server 2012
  This section contains information to help IT pros find workarounds for known issues in

Windows Server 2012 R2 and Windows Server 2012, and troubleshoot and resolve specific Windows Server 2012 R2 and Windows Server 2012 system errors and events.

- Server Roles and Technologies in Windows Server 2012 R2 and Windows Server 2012
  This section contains information to design, deploy, manage, and troubleshoot technologies in Windows Server 2012 R2 and Windows Server 2012.
- Management and Tools for Windows Server 2012 R2 and Windows Server 2012
  This section contains tool and reference information for IT pros using Windows Server 2012 R2 and Windows Server 2012. Learn about Windows PowerShell, Server Manager, Remote Server Administration Tools, and Command-Line Reference.

What's New in Windows Server

The content in this section describes what's new and changed in the latest releases of Windows Server.

- What's New in Windows Server 2012 R2
- What's New in Windows Server 2012

What's New in Windows Server 2012 R2

The content in this section describes what's new and changed in Windows Server 2012 R2. This content focuses on changes that will potentially have the greatest impact on your use of this release.

- What's New in 802.1X Authenticated Wired Access in Windows Server 2012 R2
  This topic provides information about the new features for 802.1X Authenticated Wired Access in Windows Server 2012 R2 and Windows 8.1.
- What's New in 802.1X Authenticated Wireless Access in Windows Server 2012 R2
  This topic provides information about the new features for 802.1X Authenticated Wireless Access in Windows Server 2012 R2 and Windows 8.1, including Miracast Wireless Display and faster Wi-Fi with 802.11ac.
- What's New in Active Directory in Windows Server 2012 R2
  You can leverage new features in Active Directory to enable employees and partners to access protected corporate data from their personal devices and at the same time manage risk and govern the use of corporate resources.
- **What's New in BitLocker in Windows 8.1 and Windows Server 2012 R2**
  BitLocker now provides support for device encryption on x86-based and x64-based computers with a Trusted Platform Module that supports connected standby. This topic describes the new functionality.

- What's New in Certificate Services in Windows Server 2012 R2
  Active Directory Certificate Services in Windows Server 2012 R2 supports a policy module for the Network Device Enrollment Service, TPM key attestation, and new Windows PowerShell cmdlets for backup and restore.
- What's New in Data Deduplication in Windows Server 2012 R2
  Data Deduplication can now be installed on a scale-out file share and used to optimize live virtual hard disks (VHDs) for Virtual Desktop Infrastructure (VDI) workloads. This topic describes this and other new functionality.
- What's New in DFS Replication in Windows Server 2012 R2
  This topic describes the features that were added to DFS Replication (DFSR or DFS-R) in Windows Server 2012 R2.
- What's New in DHCP in Windows Server 2012 R2
  Dynamic Host Configuration Protocol (DHCP) in Windows Server 2012 R2 provides new features and capabilities over previous versions. This document describes new deployment, manageability, and capabilities added to the DHCP Server role in Windows Server 2012 R2.
- What's New in DNS Server in Windows Server 2012 R2
  This topic provides information about new and changed functionality in the DNS Server service in Windows Server 2012 R2.
- What's New in Failover Clustering in Windows Server 2012 R2
  This topic describes the Failover Clustering functionality that is new or changed in Windows Server 2012 R2.
- New and Changed Functionality in File and Storage Services
  File and Storage Services provides a number of new management, scalability, and functionality improvements in Windows Server 2012 R2.
- What's New in File Server Resource Manager in Windows Server 2012 R2
  This topic summarizes the File Server Resource Manager functionality in Windows Server 2012 R2 that is new or changed since Windows Server 2012.
- What's New in Group Policy in Windows Server 2012 R2
  This topic describes the new and changed functionality of the Group Policy feature in Windows Server 2012 R2.
- What's New in Hyper-V for Windows Server 2012 R2
  This topic describes the new and changed functionality of the Hyper-V role in Windows Server 2012 R2.
- What's New in Hyper-V Network Virtualization in Windows Server 2012 R2
  This topic describes the new or changed features and functionality in Hyper-V Network Virtualization in Windows Server 2012 R2.
- What's New in Hyper-V Virtual Switch in Windows Server 2012 R2
  This topic provides information about the new features in Hyper-V Virtual Switch in Windows Server 2012 R2.
- What's New in IPAM in Windows Server 2012 R2
  IP Address Management (IPAM) is a feature that was first introduced in Windows Server 2012 that provides highly customizable administrative and monitoring capabilities for the IP address infrastructure on a corporate network. IPAM in Windows Server 2012 R2 includes many enhancements.

- What's New in iSCSI Target Server in Windows Server 2012 R2
  This topic describes the new and changed functionality of iSCSI Target Server in Windows Server 2012 R2.
- What's New in Networking in Windows Server 2012 R2
  This topic describes the new and changed functionality of networking in Windows Server 2012 R2.
- What's New in Print and Document Services in Windows Server 2012 R2
  This topic describes the new and changed functionality of Print and Document Services in Windows Server 2012 R2.
- What's New in Remote Access in Windows Server 2012 R2
  A number of new Remote Access server and client features are included in Windows Server 2012 R2 and Windows 8.1.
- What's New in Remote Desktop Services in Windows Server 2012 R2
  This topic describes the Remote Desktop Services functionality that is new or changed in Windows Server 2012 R2.
- New and Changed Functionality in Security and Protection in Windows Server 2012 R2
  This topic describes the significant changes to security technologies in Windows Server 2012 R2 and Windows Server 2012 and how those changes impact Windows 8.1.
- What's New in SMB in Windows Server 2012 R2
  This topic introduces the new features and functionality for Server Message Block (SMB) in Windows Server 2012 R2.
- What's New in Storage Spaces in Windows Server 2012 R2
  This topic describes the features that were added to Storage Spaces in Windows Server 2012 R2, including storage tiers, write-back cache, and dual parity.
- What's New in Windows Deployment Services in Windows Server 2012 R2
  A Windows Deployment Services (WDS) server running Windows Server 2012 R2 can be managed using the Windows PowerShell cmdlets for WDS. Using Windows PowerShell cmdlets, you can add driver packages, add client images, enable and disable boot and install images, and do many other common WDS tasks. For a full reference, see Windows PowerShell Support for Windows Server.
- What's New in Windows PowerShell
  Windows PowerShell includes several significant features that extend its use, improve its usability, and allow you to control and manage Windows-based environments more easily and comprehensively.
- **What's New in Windows Server 2012 R2 Essentials**
  The content in this section describes what's new and changed in Windows Server 2012 R2 Essentials. This content focuses on changes that will potentially have the greatest impact on your use of this release.

What's New in Windows Server 2012

The content in this section describes what's new and changed in Windows Server 2012. This content focuses on changes that will potentially have the greatest impact on your use of this release.

- What's New in Certificate Services in Windows Server 2012
  Active Directory Certificate Services (AD CS) in Windows Server 2012 provides multiple new features and capabilities over previous versions. This document describes new deployment, manageability, and capabilities added to AD CS in Windows Server 2012.
- What's New in Active Directory Domain Services (AD DS)
  Active Directory Domain Services (AD DS) in Windows Server 2012 includes new features that make it simpler and faster to deploy domain controllers (both on-premises and in the cloud), more flexible and easier to both audit and authorize access to files with Dynamic Access Control, and easier to perform administrative tasks at scale, either locally or remotely, through consistent graphical and scripted management experiences.
- What's New in Active Directory Rights Management Services (AD RMS)?
  Active Directory Rights Management Services (AD RMS) is the server role that provides you with management and development tools that work with industry security technologies—including encryption, certificates, and authentication—to help organizations create reliable information protection solutions.
- What's New in BitLocker for Windows 8 and Windows Server 2012
  BitLocker encrypts the hard drives on your computer to provide enhanced protection against data theft or exposure on computers and removable drives that are lost or stolen.
- What's New in BranchCache
  BranchCache in Windows Server 2012 and Windows 8 provides substantial performance, manageability, scalability, and availability improvements.
- What's New in DFS Namespaces and DFS Replication in Windows Server 2012
  DFS Namespaces and DFS Replication in Windows Server 2012 provide new management functionality as well as interoperability with DirectAccess and Data Deduplication.
- What's New in DHCP in Windows Server 2012
  Dynamic Host Configuration Protocol (DHCP) is an Internet Engineering Task Force (IETF) standard designed to reduce the administration burden and complexity of configuring hosts on a TCP/IP-based network, such as a private intranet.
- What's New in DNS
  Domain Name System (DNS) services in Windows Server 2012 and Windows 8 are used in TCP/IP networks for naming computers and network services. DNS naming locates computers and services through user-friendly names.
- New and changed functionality in File and Storage Services
  File and Storage Services provides a number of new management, scalability, and functionality improvements in Windows Server 2012.

- What's New in Failover Clustering in Windows Server 2012
  Failover clusters provide high availability and scalability to many server workloads. These include file share storage for server applications such as Hyper-V and Microsoft SQL Server, and server applications that run on physical servers or virtual machines.
- What's New in File Server Resource Manager in Windows Server 2012
  File Server Resource Manager provides a set of features that allow you to manage and classify data that is stored on file servers.
- What's New in Group Policy in Windows Server 2012
  Group Policy is an infrastructure that enables you to specify managed configurations for users and computers through Group Policy settings and Group Policy Preferences
- What's New in Hyper-V for Windows Server 2012
  The Hyper-V role enables you to create and manage a virtualized computing environment by using virtualization technology that is built in to Windows Server 2012. Hyper-V virtualizes hardware to provide an environment in which you can run multiple operating systems at the same time on one physical computer, by running each operating system in its own virtual machine.
- What's New in IPAM in Windows Server 2012
  IP Address Management (IPAM) is an entirely new feature in Windows Server 2012 that provides highly customizable administrative and monitoring capabilities for the IP address infrastructure on a corporate network.
- What's New in Kerberos Authentication
  The Microsoft Windows Server operating systems implement the Kerberos version 5 authentication protocol and extensions for public key and password-based authentication. The Kerberos authentication client is implemented as a security support provider (SSP) and can be accessed through the Security Support Provider Interface (SSPI).
- What's New for Managed Service Accounts
  Standalone Managed Service Accounts, which were introduced in Windows Server 2008 R2 and Windows 7, are managed domain accounts that provide automatic password management and simplified SPN management, including delegation of management to other administrators.
- What's New in Networking in Windows Server 2012
  Discover new networking technologies and new features for existing technologies in Windows Server 2012. Technologies covered include BranchCache, Data Center Bridging, NIC Teaming, and more.
- What's New in Remote Desktop Services in Windows Server 2012
  The Remote Desktop Services server role in Windows Server 2012 provides technologies that enable users to connect to virtual desktops, RemoteApp programs, and session-based desktops. With Remote Desktop Services, users can access remote connections from within a corporate network or from the Internet.
- **What's new in Security Auditing**
  Security auditing is one of the most powerful tools to help maintain the security of an enterprise. One of the key goals of security audits is to verify regulatory compliance.
- What's new in Server Manager
  In this blog post, senior Server Manager program manager Wale Martins describes the

innovations and value of the new Server Manager. Server Manager in Windows Server 2012 lets administrators manage multiple, remote servers that are running Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or Windows Server 2003.

- What's New in Smart Cards
  Smart cards and their associated personal identification numbers (PINs) are an increasingly popular, reliable, and cost-effective form of two-factor authentication. With the right controls in place, a user must have the smart card and know the PIN to gain access to network resources.
- What's New in TLS/SSL (Schannel SSP)
  Schannel is a Security Support Provider (SSP) that implements the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) Internet standard authentication protocols. The Security Support Provider Interface (SSPI) is an API used by Windows systems to perform security-related functions including authentication.
- What's New in Windows Deployment Services in Windows Server 2012
  Windows Deployment Services is a server role that enables you to remotely deploy Windows operating systems. You can use it to set up new computers by using a network-based installation.
- What's new in Windows PowerShell 3.0
  Windows PowerShell 3.0 includes many new features and improvements in the scripting and automation experience, such as Windows PowerShell Workflow, multiple new features in Windows PowerShell ISE to help make scripting and debugging faster and easier, updatable Help, Windows PowerShell Web Access, and over 2,200 new cmdlets and functions.

Technical Scenarios for Windows Server 2012 R2 and Windows Server 2012

The Technical Scenarios provide guidance that addresses an area of interest or particularly compelling capability enabled by Windows Server 2012 R2 or Windows Server 2012. Typically, multiple features or product capabilities must come together to solve a problem or address a need. The guidance in this area will grow over time as we address more scenarios and get feedback from our customers.

Windows Server 2012 R2

- Access and Information Protection
  You can leverage new features in Active Directory to enable employees and partners to access protected corporate data from their personal devices and at the same time manage risk and govern the use of corporate resources.
- **Hybrid Cloud Multi-Tenant Networking Solution Guide**
  You can connect multiple tenant networks to your network and offer secure network isolation to each tenant in a way that is simple to set up and efficient to operate.

Windows Server 2012

- Building Your Cloud Infrastructure: Scenario Overview
  You can leverage new features around network and storage virtualization that, when combined with improved server virtualization, enable the building of your cloud infrastructure based on Windows Server 2012. This will help with your strategy in delivering Infrastructure as a Service (IaaS) or building hosted services.
- Dynamic Access Control: Scenario Overview
  You can apply data governance across your file servers to control who can access information and to audit who has accessed information.
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview
  Rapid and efficient scaling of your web applications makes for a cloud-ready web platform. Enhanced security, application initialization, NUMA-aware scalability, and the sharing of resources across sites allows for this rapid scaling with minimal management overhead.
- Increasing Server, Storage, and Network Availability: Scenario Overview
  New experiences in Windows Server 2012 work together to improve availability, performance, and reliability at the single-server and multiple-server (scale-up and scale-out) levels.

Access and Information Protection

One of the most prevalent IT industry trends at the moment is the proliferation of consumer devices in the workplace. Employees and partners want to access protected corporate data from their personal devices, from checking email to the consumption of advanced business applications. IT administrators in organizations, while wanting to enable this level of productivity, would like to ensure that they can manage risk and govern the use of corporate resources.

Following are some of the cross-technology Access and Information Protection solutions you can implement in your organization:

Solution	Area	Description
Secure Access to Company Resources from any Location, on any Device	Device and Access Management	Addresses how you can implement an end-to-end solution for managing corporate-owned and personal devices, and at the same time providing secure and seamless access to corporate applications and resources.
Hybrid Identity Solution Guide – DirSync with Password Sync	Hybrid Identity	Describes a hybrid identity solution that uses DirSync with Password Sync to synchronize

Solution	Area	Description
		on-premises Active Directory with Windows Azure Active Directory.
Hybrid Identity Solution Guide – DirSync with Federation (SSO)	Hybrid Identity	Describes a hybrid identity solution that uses DirSync with AD FS and Federation (SSO) to synchronize on-premises Active Directory with Windows Azure Active Directory and provide a seamless single sign-on experience.
Dynamic Access Control: Scenario Overview	Information Protection	Provides a solution to apply data governance across corporate resources and set up policies to exercise control to who can access the data. You can also set up audit access to files for compliance reporting, and apply rights-managed protection for sensitive documents.

In addition to security and access, IT also needs to have a good strategy in place to manage PCs and personal devices from a single administrator console. Managing devices includes setting security and compliance settings, gathering software and hardware inventory, or deploying software. IT also must have a solution in place to protect the company by wiping corporate data stored on the mobile device when the device is lost, stolen, or retired from use.The solution, Manage mobile devices and PCs by migrating to Configuration Manager with Windows Intune explains in detail the Unified Device Management solution.

Manage mobile devices and PCs by migrating to Configuration Manager with Windows Intune

Building Your Cloud Infrastructure: Scenario Overview

An overview of the process for building your cloud infrastructure in Windows Server® 2012 for building an infrastructure for public and private clouds, including a scenario description, its practical applications, the roles and services that enable it, and links to topics that describe how to deploy it.

Did you mean…

1. Private cloud
2. Public cloud Software as a Service
3. Public Cloud Platform as a Service

Scenario description

The process for building your cloud infrastructure uses a combination of Hyper-V, failover clustering, storage, and networking technologies to more easily create a Microsoft cloud infrastructure. Windows Server 2012 introduces a significant number of new features that provide all of the required capabilities for building an effective cloud infrastructure in an open platform. By using automation, having an open platform, and being standards based, a Windows Server 2012-based cloud infrastructure decreases the total cost of ownership and reduces susceptibility to failures due to interoperability issues. The Windows Server 2012 open platform allows partners to extend the functionality beyond what is in the platform.

In this scenario

The following topics for the process for building your cloud infrastructure allow you to design a Hyper-V cluster for hosting the virtual machines of an IaaS cloud, configure the cloud, and then perform operations such as the on boarding of existing virtual machines and virtual machine maintenance:

- Building Your Cloud Infrastructure: Non-Converged Data Center Configuration
- Building Your Cloud Infrastructure: Converged Data Center with File Server Storage
- Building Your Cloud Infrastructure: Converged Data Center without Dedicated Storage Nodes

Practical applications

Building a cloud infrastructure with Windows Server 2012 is much easier than previous versions of Windows Server because of built-in support for the following:

- Multi-tenancy

  Designing a data center for dynamic and automatic placement of virtual machines is not enough, especially when you are serving more than one customer. Multi-tenancy is the ability of a cloud infrastructure to support the virtual machine workloads of multiple tenants, but

isolate them from each other, but all of the workloads run on the same infrastructure. The multiple workloads of an individual tenant can interconnect and be managed remotely, but these systems do not interconnect with the workloads of other tenants, nor can other tenants remotely manage them.

- Highly Scalable, Low-Cost Data Center

  You can deploy different scales of clouds, such as:

  - A mid-market business with a need for a small number of servers
  - An enterprise with hundreds or thousands of servers
  - An IaaS hosting provider with thousands of servers for multiple customers

  In all of these cases, Windows Server 2012 supports features that use low-cost alternatives to traditional data center resources that allow small clouds to be easily built, but also supports features that enable high scale operations.

- Managing and Extending the Data Center

  Windows Server 2012 simplifies data center initial configuration and ongoing management with the support of PowerShell 3.0 and PowerShell workflows. With the Hyper-V virtual switch in Windows Server 2012, vendors and partners can extend the capabilities of the virtual switch to develop additional functionality, such as network monitoring, security, or routing add-ons.

Roles and features included in this scenario

The following table lists the roles and features that are part of this scenario and describes how they support it.

Role/feature	How it supports this scenario
Hyper-V Overview	The Hyper-V server role hosts the virtual machines that make up the IT workloads running in the cloud. The process for building your cloud infrastructure takes advantage of many new features of Hyper-V in Windows Server 2012, including the Hyper-V virtual switch, live migration and storage migration improvements, Hyper-V Replica, and resource metering.
Failover Clustering Overview	The Failover Clustering feature allows a set of computers to act as a single computer, providing scale-out and failover to clustered services and resources, including storage and virtual machines. Windows Server 2012 is tightly integrated with Hyper-V and enables much of the fabric management capabilities

Role/feature	How it supports this scenario
	required for a cloud infrastructure.
File and Storage Services Overview	File and Storage Services allows a pool of storage to be made available to the cluster to assign to virtual machines and to store virtual hard disk files.
Network Adapter Teaming	The network adapter teaming feature allows you to group multiple network adapters into a team that appears as a single network adapter for bandwidth aggregation and fault tolerance.
Hyper-V Virtual Switch Overview	The Hyper-V virtual switch platform allows network partners to easily hook into the Hyper-V virtual switch network flows and build monitoring, security, and forwarding extensions.

Hardware requirements

The exact hardware requirements depend on the types of workloads you are planning to run on the Hyper-V servers in the cloud infrastructure. However, some features included in the cloud infrastructure scenarios require specialized BIOS capabilities, such as those needed to support Single Root I/O Virtualization (SR-IOV). Any technologies specific hardware requirements are discussed within the pertinent scenario..

Software requirements

Clouds based on this process for building your cloud infrastructure require Windows Server 2012 and its platform capabilities.

Designing Your Cloud Infrastructure

The Build Your Private Cloud Infrastructure Design Guide provides you with the information that you need to make informed decisions about the storage, network and compute design decision points to build a cloud infrastructure that meets the requirements of your organization. This guide provides information that you can use to assess Windows Server® 2012 platform technologies that enable a cloud-based infrastructure.

This Design Guide is focused on the design of the cloud infrastructure and the components that make up a cloud infrastructure. It does not provide information on how build a complete private cloud, public cloud, or hosted cloud infrastructure as a service (IaaS), platform as a service (PaaS), or software as a service (SaaS) solution. The cloud infrastructure contains the building blocks on which any Windows Server 2012 cloud service or delivery model is built.

This document is comprised of the following sections:

- **Cloud Infrastructure Technical Overview**. This section provides a short overview of cloud computing and the requirements of a cloud infrastructure.
- **Cloud Infrastructure Design**. This section provides an introduction to the cloud infrastructure design process.
- **Designing the Cloud Storage Infrastructure**. This section provides information related to design considerations for building the cloud storage infrastructure using Windows Server 2012 platform features and capabilities.
- **Designing the Cloud Network Infrastructure**. This section provides information related to design considerations for building the cloud network infrastructure by using Windows Server 2012 platform features and capabilities.
- **Designing the Cloud Compute (Virtualization) Infrastructure**. This section provides information related to design considerations for building the cloud compute (virtualization) infrastructure using Windows Server 2012 platform features and capabilities.
- **Overview of Suggested Cloud Infrastructure Deployment Scenarios.** This section provides information on three suggested cloud infrastructure deployment scenarios and the design decisions that drive selecting one over the other.

It should be noted from the beginning that while the terms "cloud" and "private cloud" are used throughout this document, they are used interchangeably. Private cloud, public cloud, and hybrid cloud refer to deployment models for cloud computing and it is assumed that all cloud computing infrastructures share common design considerations. This includes cloud hosting environments, which can host private or public clouds. Therefore, this documentation is topical for corporate IT organizations, private cloud hosting providers, and even public cloud providers who are interested in designing a Windows Server 2012 cloud infrastructure.

The primary focus of this Design Guide is to provide design information for the cloud infrastructure that will support the IaaS service model. Subsequent design guides will provide details on how to design, plan and implement a complete IaaS solution.

Cloud Infrastructure Technical Overview

NIST Definition of Cloud Computing

Cloud computing is a model for enabling ubiquitous, on-demand network access to a shared pool of computing resources (which include networks, servers, storage, applications, and services) that can be dynamically and rapidly provisioned and released with minimal human interaction. The United States National Institute of Standards and Technology (NIST) definition of cloud computing is one of the more popular and well-received models, and therefore is used as a basis for understanding and creating a common vocabulary and definition of cloud computing. The NIST definition includes five essential characteristics, three service models, and four deployment models.

Essential Characteristics:

- **On-demand self-service**. A consumer of the cloud service can unilaterally and automatically provision computing capabilities, such as server time and network storage, as needed without requiring human interaction with each service provider.
- **Broad network access**. The ability of a consumer of a cloud service to obtain access to cloud resources from any location, using a wide array of devices.
- **Resource pooling.** The provider's computing resources are pooled to serve multiple consumers using a multi-tenant model, with different physical and virtual resources dynamically assigned and reassigned according to consumer demand.
- **Rapid elasticity.** Capabilities can be elastically provisioned and released, in some cases automatically, to scale rapidly outward and inward commensurate with demand.
- **Measured service.** Cloud systems automatically control and optimize resource use by taking advantage of a metering capability at some level of abstraction appropriate to the type of service (for example, storage, processing, bandwidth, and active user accounts).

It should be noted that in the case of public clouds, broad network access to the cloud is crucial. Broad network access enables the cloud to be accessed through standard mechanisms that promote use by heterogeneous thin or thick client platforms (for example, mobile phones, tablets,

laptops, and workstations). Private clouds may or may not require support for broad network access.

Service Models:

- **Software as a service (SaaS).** The capability provided to the consumer is to use the cloud service provider's applications running on a cloud infrastructure.
- **Platform as a service (PaaS).** The capability provided to the consumer is to deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages, libraries, services, and tools supported by the provider.
- **Infrastructure as a service (IaaS).** The capability provided to the consumer is to provision processing (compute), storage, networks, and other fundamental computing resources where the consumer is able to deploy and run arbitrary software, which can include operating systems and applications.

Deployment Models:

- **Private cloud.** The cloud infrastructure is provisioned for exclusive use by a single organization comprising multiple consumers (for example, business units).
- **Community cloud.** The cloud infrastructure is provisioned for exclusive use by a specific community of consumers from organizations that have shared concerns (for example, mission, security requirements, policy, and compliance considerations).
- **Public cloud.** The cloud infrastructure is provisioned for open use by the general public. It might be owned, managed, and operated by a business, academic, or government organization, or some combination of those.
- **Hybrid cloud.** The cloud infrastructure is a composition of two or more distinct cloud infrastructures (private, community, or public) that remain unique entities, but are bound together by standardized or proprietary technology that enables data and application portability (for example, cloud bursting for load balancing between clouds).

It is important to note that there is no specific alignment between cloud service and delivery models. Any service model can be instantiated using any of the delivery models. For example, while Software as a Service (SaaS) is often considered a public cloud service model, there is no reason why SaaS cannot be delivered in an on-premises or hosted private cloud.

For more information and a detailed discussion of the NIST definition of private cloud, please see the NIST Definition of Cloud Computing.

Microsoft Private Cloud Overview

Private cloud is a computing model that uses infrastructure dedicated to your organization. A private cloud shares many of the characteristics of public cloud computing including resource pooling, self-service, elasticity, and metered services delivered in a standardized manner with the additional control and customization available from dedicated resources.

The only fundamental difference between a private cloud and a public cloud is that a public cloud provides cloud resources to multiple organizations while the private cloud hosts resources for a

single organization. However, a single organization may have multiple business units and divisions which can lend itself to being multi-tenant in nature. In these circumstances, private cloud shares many of the security and isolation requirements of public cloud.

While virtualization is an important technological enabler of private cloud, the key differentiator is the continued abstraction of computing resources from the infrastructure and the machines (virtual or otherwise) used to deliver those resources. Only by delivering this abstraction can you achieve the benefits of cloud computing—including improved agility and responsiveness, reduced total cost of ownership (TCO), and increased business alignment and focus. Most importantly, a private cloud promises to exceed the cost effectiveness of a virtualized infrastructure through higher workload density and greater resource utilization.

The Microsoft Private Cloud is a unique and comprehensive offering, built on four key "pillars."

- **All About the App:** Application-centric cloud platform that helps you focus on business value.
- **Cross-Platform from the Metal Up:** Cross-platform support for multi-hypervisor environments, operating systems, and application frameworks.
- **Foundation for the Future:** Microsoft Private Cloud lets you go beyond virtualization to a true cloud platform.
- **Cloud on Your Terms:** Ability to consume cloud on your terms, providing you the choice and flexibility of a hybrid cloud model through common management, virtualization, identity, and developer tools.

For further reading on the Microsoft Private Cloud, please see Microsoft Private Cloud Overview

Windows Server 2012 Cloud Infrastructure for Hosting Environments

A Microsoft cloud infrastructure forms the core compute, storage and networking capabilities that power any of the cloud service or delivery models. This means that, in addition to enterprises, cloud service providers (CSPs) or private cloud hosters can also take advantage of the core Windows Server 2012 platform cloud technologies to build hosted cloud solutions to support hosted private and public cloud solutions. The many innovations included with Windows Server 2012 enable you to deliver the security, isolation, performance, availability and scalability hosters require for providing commercial cloud services.

Private Cloud Architecture Principles

Private cloud principles provide general rules and guidelines to support the evolution of a cloud infrastructure, whether they be on-premises or in a hosted cloud environment. They are enduring, seldom amended, and inform and support the way a cloud fulfills its mission and goals. They also strive to be compelling and aspirational in some respects, since there needs to be a connection with business drivers for change. These principles are often interdependent and together form the basis on which a cloud infrastructure is planned, designed, and created:

- Resource Pooling
- Elasticity and Perception of Infinite Capacity

- Perception of Continuous Availability
- Drive Predictability
- Metering/Chargeback (Service Provider's Approach to Delivering IT)
- Multi-tenancy
- Security and Identity

All decisions regarding how the cloud infrastructure is designed should keep the principles in mind. For a detailed discussion of the private cloud principles, please see Private Cloud Principles, Concepts, and Patterns.

The Private Cloud Reference Model

IaaS is an application of the private cloud architecture principles to deliver a cloud infrastructure. You can use the reference model displayed in the following figure to ensure that you are delivering a holistic solution that spans all the layers required for a mature IaaS solution. The model acts as the "guide-rails" to assist cloud infrastructure designers' and architects' efforts to holistically address the development of a private cloud architecture. This model is used as a reference only, and some pieces are emphasized more than others in the technical reference architecture based on experience operating private clouds in real-world environments.

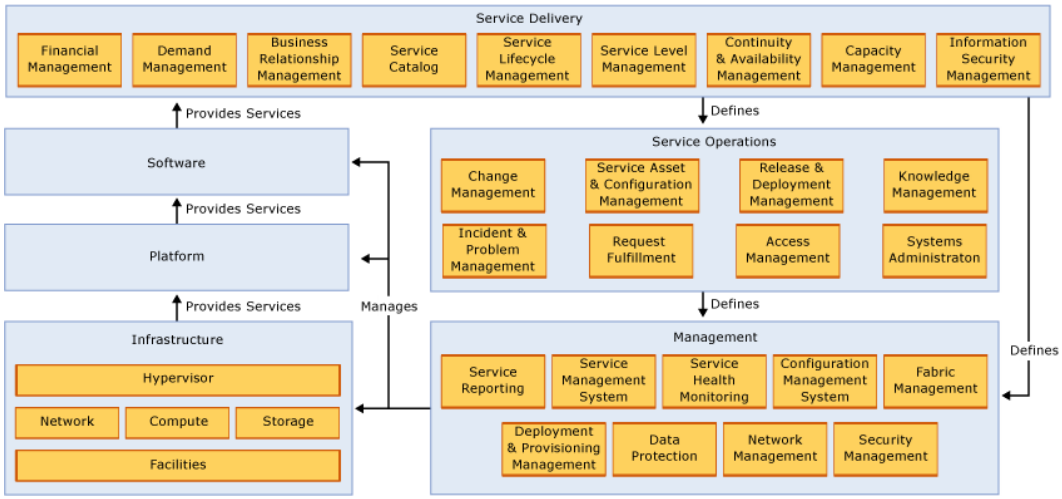

Figure 1. The private cloud reference model—IaaS view

The primary focus of this document is on the Infrastructure section of the Private Cloud Reference Model, where the focus is on the core network, compute, and storage components that let you build a cloud-ready infrastructure. However, we do not cover issues that apply to facilities considerations.

For more information and comprehensive coverage of the private cloud reference model, please see Private Cloud Reference Model.

Conceptual Architecture—Infrastructure

One of the key drivers of the layered approach to the infrastructure architecture presented here is to enable complex workflow and automation to be developed over time by creating a collection of simple automation tasks, assembling them into procedures that are managed by the management layer, and then creating workflows and process automation that are controlled by the orchestration layer. However, before you can implement these key features of a cloud solution, you need to understand key definitions and design points relevant to a well architected cloud infrastructure. The cloud infrastructure should address the following components:

1. Scale Units
2. Storage
3. Networking
4. Virtualization platform

Scale Units

In a modular architecture, the concept of a scale unit refers to the point where a module in the architecture can scale to before another module is required. For example, an individual server is a scale unit, it can be expanded to a certain point in terms CPU and RAM but beyond its maximums, an additional server is required to continue scaling. Each scale unit also has an associated amount of physical installation labor, configuration labor, and other labor overhead. With large scale units such as a pre-configured full rack of servers, the labor overhead can be minimized. When designing a cloud infrastructure, care should be taken to define the size of a scale unit.

Server scale limits are well published and include number and speed of CPU cores, maximum amount and speed of RAM, number and type of expansion slots, and so on. Particularly important are the number and type of onboard input/output (I/O) ports and the number and type of supported I/O cards. Infiniband, Ethernet, SAS (Serial Attached SCSI) and Fibre Channel expansion cards often provide multi-port options where a single card can have 4 ports. Additionally, in blade server architectures, there are often limitations in the amount of I/O card and/or supported combinations. It is important to be aware of these limitations and the oversubscription ratio between blade I/O ports and any blade chassis switch modules.

A single server is not a good scale unit for a private cloud solution due to the amount of overhead required to install and configure an individual server. Instead, scale units should be designed with considerations regarding historical rates of growth and how often your organization wants to add capacity to the infrastructure while providing adequate lead time so that overall service levels are not negatively impacted at any point in time. Instead, scale units should be designed with considerations regarding historical rates of growth and how often your organization wants to add capacity to the infrastructure while providing adequate lead time so that overall service levels are not negatively impacted at any point in time. Scale units should also take advantage of the private cloud principle of homogeneity.

For more information about scale units, please the Private Cloud Principles, Concepts, and Patterns.

Storage

Storage architecture is a critical design consideration for private cloud solutions. Storage and supporting storage networking are critical to the overall performance of the environment in addition to the overall cost, because storage tends to be one of the more costly items.

Storage architectures today have several layers including the storage array(s), the storage network, the storage protocol, and for virtualization, the file system utilizing the physical storage.

The traditional approach to storage arrays and storage protocols was to install a Storage Area Network (SAN) solution directly connected to the cloud compute (virtualization) cluster using either iSCSI or Fibre Channel. This storage design pattern provided for the key performance, reliability, availability and scalability requirements for enterprise storage, all of which are critical factors when considering storage design for a cloud infrastructure.

Windows Server 2012 provides a new option that can satisfy these cloud infrastructure storage requirements: Storage Spaces. Storage Spaces in Windows Server 2012 enables cost-effective, optimally used, highly available, scalable, and flexible storage solutions for business-critical (virtual or physical) deployments. You can use cost-effective SAS drives in a JBOD (Just a Bunch of Disks) enclosure with Storage Spaces and benefit from many of the same capabilities of expensive SAN-based storage arrays.

Historically, iSCSI and Fibre Channel have been the storage protocols of choice. However, Windows Server 2012 offers another option – file based storage over SMB 3.0. Using this approach, you can create separate compute and storage clusters that enable you to scale compute and storage independently. This also has the potential to greatly simplify your cloud infrastructure as management of file shared based storage is typically simpler than SAN storage. The SMB 3.0 protocol makes it possible for the compute cluster to access the storage cluster at near Direct Attached Storage (DAS) speeds over a 10 Gbps network fabric.

In addition to highly available storage over SMB 3.0, Windows Server 2012 cloud infrastructure administrators have the option to use another file based storage option – NFS high-availability transparent failover. This makes it possible to deploy Server for NFS in a clustered configuration and take advantage of better resilience to hardware and software outages that may afflict individual cluster nodes.

We will cover detailed cloud storage infrastructure design decisions later in this document.

Networking

Many network architectures include a tiered design with three or more tiers such as core, distribution, and access. Designs are driven by the port bandwidth and quantity required at the edge, in addition to the ability of the distribution and core tiers to provide higher speed uplinks to aggregate traffic. Additional considerations include Ethernet broadcast boundaries and limitations, spanning tree or other loop-avoidance technologies.

A dedicated management network is a frequent feature of advanced data center virtualization solutions. Most virtualization vendors recommend that hosts be managed via a dedicated network so that there is no competition with tenant traffic and to provide a degree of separation for security and ease of management purposes. This historically implied dedicating a network

adapter per host and port per network device to the management network. However, with new technologies included with Windows Server 2012, dedicating network adapters to each traffic class is no longer required or recommended. Windows Server 2012 includes new capabilities that enable you to converge your network traffic classes to a single NIC or NIC team. .

With advanced data center virtualization, a frequent use case is to provide isolated networks where different owners such as particular departments or applications are provided their own dedicated networks. In the past, multi-tenant networking referred to using technologies such as virtual local area networks (VLANs) or Internet Protocol Security (IPsec) isolation techniques to provide dedicated networks that utilize a single network infrastructure or wire. However, VLANs are complex to configure and manage, and are not scalable past 4094 VLANs. Windows Server 2012 Hyper-V includes a number of improvements in the Hyper-V virtual switch that enable you to get the isolation you need without using VLANs by providing new features such as Private VLANs (PVLANs), Port ACLs and virtual networking, sometimes referred to as software defined networking (SDN).

Managing the network environment in a private cloud can present challenges that must be addressed. Ideally, network settings and policies are defined centrally and applied universally by the management solution, such as the Virtual Machine Manager component of Microsoft System Center 2012 with Service Pack 1 (SP1). In the case of IPsec-based isolation, this can be accomplished using Active Directory Domain Services (AD DS) and Active Directory Group Policy to control firewall settings across the hosts and guests, in addition to the IPsec policies controlling network communication. In addition, you can optimize VM density when using IPsec because Windows Server 2012 now includes support for IPsec Talk Offload (IPsecTO) for guest virtual machines.

For VLAN-based network segmentation, several components including the host servers, host clusters, Virtual Machine Manager, and the network switches must be configured correctly to enable both rapid provisioning and network segmentation. With Hyper-V and host clusters, identical virtual switches should be defined on all nodes in order for a virtual machine to be able to failover to any node and maintain its connection to the network. At large scale, this can be accomplished via Windows PowerShell scripting.

In a Windows Server 2012–based cloud infrastructure, VLAN assignments are typically limited to the major traffic classes; these are the host traffic and tenant traffic classes. Bandwidth guarantees can be assigned using Windows Server 2012 Quality of Service (QoS) so that subclasses of traffic, such as cluster traffic, management traffic, live migration traffic, and storage traffic, have the bandwidth they require. In addition, it's important to minimize or avoid the use of VLANs for tenant traffic, as VLANs exclude the option of using Windows Server 2012 Network Virtualization. We will discuss cloud infrastructure network design decisions in detail later in this document.

Virtualization Platform

The virtualization layer is one of the primary enablers for private cloud. The decoupling of hardware, operating systems, data, applications, and user state opens a wide range of options for optimal management and distribution of workloads across the physical infrastructure. Windows

Server 2012 Hyper-V provides the ability to migrate running virtual machines from one server to another with zero downtime and many other Hyper-V features that provide a rich set of capabilities. These capabilities can be utilized by the automation, management, and orchestration layers to maintain desired states (such as load distribution) or to proactively address decaying hardware or other issues that would otherwise cause faults or service disruptions.

As with the hardware layer, the virtualization layer must be able to be managed by the automation, management, and orchestration layers. The abstraction of software from hardware that virtualization provides moves the majority of management and automation into the software space, instead of requiring you to perform manual operations on physical hardware.

Cloud Infrastructure Design

In the next three sections we will discuss design considerations and options for designing a cloud infrastructure using Windows Server 2012 platform capabilities. This discussion will include design discussions around:

1. Storage architecture
2. Network architecture
3. Compute (virtualization and cluster) architecture

After a review of the design decisions you will need to make around the storage, network and compute architectures, there will be a discussion on three design patterns that based on key design decisions made in each of these domains.

Designing the Cloud Storage Infrastructure

The storage design for any virtualization-based solution is a critical element that is typically responsible for a large percentage of the solution's overall cost, performance, and agility.

The storage solution should provide transport-independent, seamless data access using block-level and/or file-level protocols from the same platform. A storage solution can provide block-level data access over a Fibre Channel SAN fabric using Fibre Channel Protocol (FCP) and over an IP-based Ethernet network using iSCSI or Fibre Channel over Ethernet (FCoE). Infiniband is another option for high performance storage networking. File-access protocols such as NFS, SMB 3.0, HTTP, or FTP provide file-level access over an IP-based Ethernet network.

Storage Options

This section discusses a number of storage options available to you that will inform some key design decisions you need to make when considering alternatives. Specific options discussed include:

1. Storage protocols
2. Storage network
3. Cluster Shared Volumes (CSVs)

Storage Protocols

Although many storage options exist, organizations should choose their storage devices based on their specific data-management needs. Storage devices are typically modular and flexible midrange and high-end SANs. Modular midrange SANs are procured independently and can be chained together to provide greater capacity. They are efficient, can grow with the environment as needed, and require less up-front investment than high-end SANs. Large enterprises and hosters might have larger storage demands and might need to serve a larger set of customers and workloads. In this case, high-end SANs can provide the highest performance and capacity. High-end SANs typically include more advanced features such as continuous data availability through technologies like replication and clustering. However, the price of these high-end SANs can be prohibitive, and you should factor in the costs with the value provided over other options.

Fibre Channel has historically been the storage protocol of choice for enterprise data centers for a variety of reasons, including good performance and low latency. Over the past several years, however, the advancing performance of Ethernet from 1 Gbps to 10 Gbps and beyond has led to great interest in storage protocols that make use of Ethernet transport—such as iSCSI, and more recently FCoE. SMB 3.0 can also be used for file based storage access and provide the same or superior performance when compared to iSCSI of FCoE.

A key advantage of the protocols that use the Ethernet transport is the ability to use a "converged" network architecture in which a single Ethernet infrastructure serves as the transport for both LAN and storage traffic. FCoE is an emerging technology that brings the benefits of using an Ethernet transport while retaining the advantages of the Fibre Channel protocol and the ability to use Fibre Channel storage arrays. SMB 3.0 can be used to connect to file servers that host virtual machine files. Windows Server 2012 is designed to fully support a converged network infrastructure.

In the past a common practice in large-scale Hyper-V deployments was to use both Fibre Channel and iSCSI. Fibre Channel and iSCSI can provide the host storage connectivity. Similarly, both Fibre Channel and iSCSI can be used directly by guests—for example, for the shared disks in a guest cluster. This is made possible by the new Windows Server 2012 feature that surfaces Fibre Channel HBAs to guest virtual machines. In Windows Server 2012 SMB 3.0 can provide the same advantages. In addition, with Windows Server 2012 you can take advantage of a new storage option called Storage Spaces where you can attach SAS JBODs to a file server cluster and access the virtual machine files from the compute cluster from over the Ethernet network.

Note

Windows Server 2012 now supports Offload Data Transfer (ODX) which is a new high performance storage protocol that significantly reduces the processing and time it takes to copy files from one storage unit to another. You can learn more about ODX at Windows Offloaded Data Transfers overview.

Storage Network

iSCSI, SMB 3.0 and FCoE use an Ethernet transport for storage networking. This provides another architecture choice in terms of whether to use a dedicated Ethernet network with

separate switches, cables, paths, and other infrastructure or, instead, to use a converged network in which multiple traffic types are run over the same cabling and infrastructure.

The storage solution must provide logical or physical isolation between storage and Ethernet I/O. If it's a converged network, QoS must be provided to guarantee storage performance. The storage solution must provide iSCSI or Fibre Channel connectivity for guest clustering and fully redundant, independent paths for storage I/O.

Standards-based converged network adapters, switches, and Fibre Channel storage arrays should be used for FCoE. If iSCSI, FCoE or SMB 3.0 is used, you can assign a dedicated network adapter for storage traffic or use Windows Server 2012 new Hyper-V switch capabilities to create a converged network infrastructure.

Cluster Shared Volumes

CSVs (Cluster Shared Volumes) provide a distributed file-access solution so that multiple nodes in the cluster can simultaneously access the same NTFS file system. For example, virtual machines that are distributed across multiple cluster nodes can access their virtual hard disk (VHD) files, even if the VHD files are on a single disk (logical unit number [LUN]) in storage. This also enables virtual machines to move to any node in the cluster, since each cluster node has access to files contained in the CSV. The clustered virtual machines can also all fail over independently of one another and no longer present themselves as a single resource group.

The following is a partial list of new CSV functionality in Windows Server 2012 that you can use to when designing the shared storage infrastructure for your private cloud:

- Storage system for scale-out file servers, which can provide continuously available and scalable file-based SMB server application storage. The scale-out file server feature is used when you choose to host the virtual machine files in a storage cluster. For more information, see Support for scale-out file servers.
- A single consistent file name space, with CSV volumes that now appear as CSV File System (CSVFS). The underlying technology is still the NTFS file system, and volumes are still formatted with NTFS. In a clustered environment, the CSV must be formatted as NTFS as ReFS is not supported on CSVs in Windows Server 2012.
- Direct I/O for file data access, including sparse files, which enhances virtual machine creation and copy performance. Redirected I/O is used when Storage Spaces is deployed using either mirrored or parity based resiliency.
- No external authentication dependencies, which provides improved performance and resiliency. The cluster can now start and the CSV will be mounted even if an Active Directory domain controller is not available when the cluster reboots.
- Support for SMB 3.0 storage for Hyper-V and applications such as SQL Server. For more information on SMB 3.0 functionality, see Server Message Block overview.
- Integration with SMB Multichannel and SMB Direct, which allow CSV traffic to stream across multiple networks in the cluster and to take advantage of network adapters that support remote direct memory access (RDMA). SMB also provides for transparent failover so that in the event that a member of the file server cluster becomes unavailable, connections to the virtual machine files continue to be available and with no downtime.

- Support for BitLocker Drive Encryption for CSVs in addition to traditional cluster disks. This is particularly useful when clusters are deployed in branch offices and other low security environments.
- The capability to make storage visible to only a subset of nodes, which enables scenarios for a single cluster that contains application and data nodes. This is an example of an "asymmetric storage cluster". In this design pattern, some of the nodes in the cluster are connected to storage and some of the nodes are dedicated to the compute role. The compute nodes then connect to file based storage over the SMB 3.0 protocol.
- Integration with the Storage Spaces feature in Windows Server 2012, which can provide virtualized storage on clusters of inexpensive SAS disks. For more information about Storage Spaces, see File and Storage Services overview.
- Ability to scan and repair volumes with zero offline time due to new capabilities deliver by the Windows Server 2012 CHKDSK application. For more information on advances in CHKDSK, please see Multi-terabyte volumes.

CSVs provide not only shared access to the disk, but also storage path I/O fault tolerance (dynamic I/O redirection). In the event the storage path on one node becomes unavailable, the I/O for that node will be rerouted via SMB 3.0 through another node. This feature can use any Cluster Communications Network and further increases the need for high-speed 10 GB Ethernet networks.

CSVs maintain metadata information about the volume access and require that some I/O operations take place over the cluster communications network. One node in the cluster is designated as the coordinator node and is responsible for these disk operations. Virtual machines, however, have direct I/O access to the volumes, and only use the dedicated storage paths for disk I/O, unless a failure scenario occurs as described above. The exception to this is with Storage Spaces when resiliency is added to the CSV.

CSV Requirements

Requirements for implementing a Windows Server 2012 private cloud that uses CSVs include:

- All cluster nodes must use Windows Server 2012.
- All cluster nodes must use the same drive letter for the system disk.
- All cluster nodes must be on the same logical network subnet.
- SMB must be enabled for each network on each node that will carry CSV cluster communications.
- "Client for Microsoft Networks" and "File and Printer Sharing for Microsoft Networks" must be enabled in the network adapter's properties to enable all nodes in the cluster to communicate with the CSV.
- The Hyper-V role must be installed on any cluster node that might host a virtual machine.

Note that when you configure the failover cluster using the failover cluster wizard, most of these configuration requirements will be handled for you.

CSV Volume Sizing

Because all cluster nodes can access all CSV volumes simultaneously, you can now use standard LUN allocation methodologies based on performance and capacity requirements of the workloads running within the virtual machines themselves. In general, it's considered a good idea to isolate the virtual machine operating system I/O from the application data I/O, in addition to application-specific I/O considerations such as segregating databases and transaction logs and creating SAN volumes and/or Storage Spaces–based storage pools that factor in the I/O profile itself (for example, random read and write operations versus sequential write operations).

CSV architecture differs from traditional clustered file systems, which frees it from common scalability limitations. As a result, there is no special guidance for scaling the number of Hyper-V nodes or virtual machines on a CSV volume other than ensuring that the overall I/O requirements of the expected virtual machines running on the CSV are met by the underlying storage system and storage network.

While rare, disks and volumes can enter a state where a chkdsk is required, which with large disks can take a long time to complete, causing downtime of the volume during this process somewhat proportional to the volume's size. However, significant improvements have been made to the chkdsk feature in Windows Server 2012 so that for even very large volumes with tens of millions of files, it should not take more than a minute to complete the check.

Each enterprise application you plan to run within a virtual machine can have unique storage recommendations and even perhaps virtualization-specific storage guidance. That guidance applies to use with CSV volumes as well. The important thing to keep in mind is that all virtual machine virtual disks running on a particular CSV will contend for storage I/O.

Also worth noting is that individual SAN LUNs do not necessarily equate to dedicated disk spindles. A SAN Storage Pool or redundant array of independent disks (RAID) array can contain many LUNs. A LUN is simply a logical representation of a disk provisioned from a pool of disks. Therefore, if an enterprise application requires specific storage I/O per second (IOPS) or disk-response times you must consider all the LUNs in use on that Storage Pool. An application which would require dedicated physical disks were it not virtualized might require dedicated Storage Pools and CSV volumes running within a VM.

Note

When considering the use of Storage Spaces to host your CSVs, you might want to consider the fact that when enabling resiliency for the CSV, only a single node can write to it directly; the other nodes will use I/O redirection to the coordinator node in this scenario. For this reason, you may want to create multiple CSVs (perhaps one per cluster member) and distribute your virtual machine files across the CSVs so that a single node does not receive a disproportionate amount of network traffic due to I/O redirection.

CSV Design Patterns

Single CSV per Cluster

In the Single CSV per Cluster design pattern, storage is configured to present a single large LUN to all the nodes in the cluster. The LUN is configured as a CSV in Failover Clustering. All virtual-machine related files (such as VHDs and configuration files) belonging to the virtual machines hosted on the cluster are stored on the CSV. Optionally, data deduplication functionality provided by the SAN or the Windows Server 2012 deduplication feature can be utilized. Note that when you configure a file server cluster using the scale-out file server capability, Windows Server 2012 deduplication will not be available. However, you can still take advantage of Windows Server 2012 data deduplication in your virtual machine libraries.

Multiple CSVs per Cluster

In the Multiple CSVs per Cluster design pattern, storage is configured to present two or more large LUNs to all the nodes in the host cluster. The LUNs or Storage Spaces virtual disks are configured as a CSV in Failover Clustering. All virtual-machine related files (such as VHDs and configuration files) belonging to the virtual machines hosted on the cluster are stored on the CSVs. Optionally, data deduplication functionality provided by the SAN or Windows Server 2012 deduplication can be utilized, with some limitations as previously mentioned.

For both the Single and Multiple CSV patterns, each CSV has the same I/O characteristics, so each individual virtual machine has all its associated VHDs stored on one of the CSVs. Alternatively, you can use storage tiering and assign CSVs to different tiers. This is useful if you want to present storage options as part of your private cloud service catalog.

Multiple I/O Optimized CSVs per Cluster

In the Multiple I/O Optimized CSVs per Cluster design pattern, the SAN is configured to present multiple LUNs or Storage Spaces virtual disks to all the nodes in the cluster but they are optimized for particular I/O patterns such as fast sequential read performance, or fast random write performance. The volumes are configured as CSVs in Failover Clustering. All VHDs belonging to the virtual machines hosted on the cluster are stored on the CSVs but targeted to the most appropriate CSV for the given I/O needs.

In the Multiple I/O Optimized CSVs per Cluster design pattern, each individual virtual machine has all its associated VHDs stored on the appropriate CSV following required I/O requirements.

Note that a single virtual machine can have multiple VHDs, and each VHD can be stored on a different CSV (provided all CSVs are available to the host cluster the virtual machine is created on).

In addition, you can further optimize the CSV I/O by taking advantage of CSV read caching with write through. Learn more about this capability at How to enable CSV Cache.

Storage Design

A highly available storage design, which could use either a SAN or SAS-based JBOD solution and Storage Spaces, should have no single points of failure, including:

- Redundant power from independent power distribution units (PDUs)
- Redundant storage controllers
- Redundant storage paths (supported, for example, by redundant target ports of network adapters per controller, redundant Fibre Channel or IP network switches, and redundant cabling)
- Data storage redundancy similar to what occurs with volume mirroring or parity, or synchronous or asynchronous replication

You will need to address the following elements when designing or modifying your storage solution as the basis of your Microsoft Private Cloud storage infrastructure:

- Performance
- Drive types
- Multipathing
- Fibre Channel SAN
- iSCSI SAN
- Storage Spaces
- Data deduplication
- Thin provisioning
- Volume cloning
- Volume snapshot

Performance

Storage performance is a mix of drive, interface, controller, cache, protocol, SAN, host bus adapter (HBA), driver, and operating system considerations. The overall performance of the storage architecture is typically measured in terms of maximum throughput and/or maximum IOPS for a given latency or response time. Although each of these performance measurements is important, IOPS for a given latency is the most relevant to server virtualization in private cloud environments.

Another important consideration is what type of cloud infrastructure do you want to provide? In most cases the private cloud will present a general purpose infrastructure that is not designed around specific workloads. Workloads that require specific disk performance characteristics that lie outside the capabilities of a general purpose private cloud infrastructure may be better served by creating a dedicated infrastructure for those workloads.

Drive Types

The type of hard drive used in the host server or the storage array has the most significant impact on the overall storage architecture performance. As with storage connectivity, high IOPS and low latency are more critical than maximum sustained throughput when it comes to host server sizing and guest performance. When selecting drives, this translates into selecting those with the highest rotational speed and lowest latency possible. Using 15K revolution per minute (RPM) drives over 10K RPM drives can result in up to 35 percent more IOPS per drive.

You will also want to consider storage tiering, so that you can provide options to consumers of the cloud service. A storage tiering scheme might include a high-performance tier, a medium-performance tier, and a high-capacity tier. These tiers can be included in the service catalog. Windows Server 2012 includes support for newer 4K high-capacity drives, which can be part of one or more storage tiers. In addition, SSD drives will become the norm in the future as prices continue to come down on this ultra-fast storage option.

Multipathing

In order to support a highly resilient private cloud storage infrastructure, multipathing should be used. Among the features enabling high availability for connecting servers based on Windows to SANs is integrated Multipath I/O (MPIO) support. Microsoft MPIO architecture supports iSCSI, Fibre Channel, and SAS SAN connectivity by establishing multiple sessions or connections to the storage array. Multipathing solutions use redundant physical path components—adapters, cables, and switches—to create logical paths between the server and the storage device. In the event that one or more of these components fails, causing the path to fail, multipathing logic uses an alternate path for I/O so that applications can still access their data. Each Ethernet interface or HBA should be connected by using redundant switch infrastructures to provide continued access to storage in the event of a failure in a storage fabric component.

Failover times vary by storage vendor, and can be configured by using timers in the Microsoft iSCSI Software Initiator driver, or modifying the Fibre Channel host bus adapter driver parameter settings.

Fibre Channel SAN

Fibre Channel is a robust and high-speed storage protocol that supports multipathing through Microsoft Windows Server 2012 MPIO. Windows Server 2012 provides Fibre Channel ports for both host and guest operating systems. Support for guest operating system connectivity through Fibre Channel is new in Windows Server 2012 and allows you to connect to Fibre Channel directly from within virtual machines. This feature enables you to virtualize workloads that use direct access to Fibre Channel storage and allows you to cluster guest operating systems over Fibre Channel.

Mid-range and high-end storage arrays are capable of advanced storage functionality that helps offload certain management tasks from the hosts to the SANs. Virtual Fibre Channel presents an alternate hardware-based I/O path to the Windows software virtual hard disk stack. This allows you to use the advanced functionality offered by your Fibre Channel SANs directly from Hyper-V virtual machines. For example, you can use Hyper-V to offload storage functionality (for example, taking a snapshot of a LUN) on the SAN hardware by using a hardware volume shadow copy service (VSS) provider from within a Hyper-V virtual machine.

Windows Server 2012 Hyper-V allows you to define virtual SANs on the host to accommodate scenarios where a single Hyper-V host is connected to different SANs through multiple Fibre Channel ports. A virtual SAN defines a named group of physical Fibre Channel ports that are connected to the same physical SAN. For example, assume that a Hyper-V host is connected to two SANs—a production SAN and a test SAN. The host is connected to each SAN through two

physical Fibre Channel ports. In this example, you might configure two virtual SANs—one named "Production SAN" that has the two physical Fibre Channel ports connected to the production SAN, and one named "Test SAN" that has two physical Fibre Channel ports connected to the test SAN. You can use the same technique to name two separate paths to a single storage target.

You can configure as many as four virtual Fibre Channel adapters on a virtual machine and associate each one with a virtual SAN. Each virtual Fibre Channel adapter connects with one WWN address or two WWN addresses to support live migration. You can set each WWN address automatically or manually.

Hyper-V in Windows Server 2012 can use the multipath I/O (MPIO) functionality to ensure continuous connectivity to Fibre Channel storage from within a virtual machine.

You can use MPIO functionality with Fibre Channel in the following ways:

- Virtualize workloads that use MPIO. Install multiple Fibre Channel ports on the host, and use MPIO to provide highly available connectivity to the LUNs accessible by the host.
- Configure multiple virtual Fibre Channel adapters inside a virtual machine, and use a separate copy of MPIO within the guest operating system of the virtual machine to connect to the LUNs that the virtual machine can access. This configuration can coexist with a host MPIO setup.
- Use different DSMs for the host or each virtual machine. This approach allows live migration of the virtual machine configuration, including the configuration of DSM and connectivity between hosts and compatibility with existing server configurations and DSMs.

iSCSI SAN

Unlike a Fibre Channel–connected SAN, which is on its own Fibre Channel network, the iSCSI SAN can be on its own isolated Ethernet or Infiniband network or it can benefit from Windows Server 2012 capabilities that enable converged networking to support isolation that is so critical in a multi-tenant architecture. Any networking standard practice method for achieving this goal is acceptable, including a physically separate, dedicated storage network and a physically shared network with the iSCSI SAN running on a private VLAN. Alternatively, you can use new QoS and port access control list (ACL) features in Windows Server 2012 to converge the storage network with other non-tenant and tenant network flows.

In Windows Server 2012, the iSCSI Software Target is available as a built-in feature under the File and Storage Service role. As an inbox feature, the management experience is integrated with Server Manager and the failover cluster management console.

When used in a cloud infrastructure, the iSCSI Software Target is ideal for:

- **Network/diskless boot:** By using boot-capable network adapters or a software loader, you can deploy hundreds of diskless host servers. This is ideal for large deployments of identical operating system images, such as a Hyper-V compute cluster.
- **Server application storage:** Some applications require block storage. The iSCSI Software Target can provide these applications with continuously available block storage. Since the storage is remotely accessible it can also consolidate block storage for central or branch office locations.

- **Heterogeneous storage:** iSCSI Software Target supports non-Windows iSCSI initiators, making it easy to share storage on Windows Servers in a mixed environment.
- **Development/test/demo/lab clouds:** When the iSCSI Software Target feature is enabled, it turns any server running Windows Server into a network-accessible block storage device. This is ideal for testing applications prior to deployment on SAN storage.

Enabling Microsoft iSCSI Software Target to provide block storage takes advantage of your existing Ethernet network. No additional hardware is needed. To obtain high availability, consider setting up a highly available storage cluster. With a highly available storage cluster, you will need shared storage for the cluster—such as Fibre Channel storage or an SAS storage array, which can be configured to use Storage Spaces.

If you enable guest clustering, you need to provide block storage. Any servers running Windows Server software with Microsoft iSCSI Software Target can provide block storage. An iSCSI Target Server enables you to network boot multiple computers from a single operating system image that is stored in a centralized location. iSCSI Software Target in Windows Server 2012 can boot hundreds of computers by using a single operating system image, and it provides the several key benefits.

For example, by using differencing virtual disks, you can use a single operating system image (the "golden image") to boot up to 256 computers. In a deployment of Windows Server 2008 R2 HPC Edition, the operating system image is approximately 20 GB. A common deployment is to have two mirrored disk drives that act as the boot volume. Rounding the operating system storage to 40 GB per instance, you would need approximately 10 TB of storage—for only the operating system image—to boot 256 computers. With iSCSI Software Target boot, however, you will use 40 GB for the operating system base image, and 2 GB for differencing virtual hard disks (VHDs) per server instance, totaling 552 GB for the operating system images. This provides a savings of over 90 percent on storage for the operating system images alone.

Other advantages to using Windows Server 2012 iSCSI Target Boot in your private cloud storage infrastructure include:

- **Controlled operating system images make it more secure and easy to manage.** Some enterprises require that data be secured by physically locking storage in a centralized location. In this scenario, servers access the data remotely, including the operating system image. With iSCSI Software Target boot, you can centrally manage the operating system boot images, and control which applications to put in the golden image.
- **Rapid deployment.** Because the golden image is a sysprepped operating system image, when the computers boot from the golden image, they skip the file copying and installation phase that occurs during Windows Setup, and they go straight to the customization phase. In our testing, we deployed 256 computers in 34 minutes.
- **Fast recovery.** Because the operating system images are hosted on the iSCSI Target Server, if the diskless client needs to be replaced, the new computer can point to the operating system image, and boot up immediately.
- **Centralized updating of the golden image.** You can update all host systems in your private cloud by updating the golden image. When cluster members are restarted they reboot from the new golden image. Post-boot tasks can be integrated into the cloud fabric controller so that the updated server is joined back into the cluster.

SAN boot is a solution that has been offered from various vendors. Now with Windows Server 2012, the new iSCSI Software Target feature provides this network boot capability on commodity hardware which can lead to significant cost savings since there are no special hardware requirements. In data centers with large-scale deployments, the design should be validated against specific hardware.

Note

For reference, Microsoft internal testing indicated that for a 256-iSCSI boot deployment, 24 x 15k-RPM disks in a RAID 10 configuration were required for storage. A network bandwidth of 10 GB is optimal. A general estimate is 60 iSCSI boot servers per 1 GB network adapter. However, an iSCSI boot-capable network adapter is not required for this scenario. If the network adapter does not support it, a software boot loader can be used (such as iPXE open source boot firmware).

Storage Spaces

Storage Spaces in Windows Server 2012 enables cost-effective, optimally used, highly available, scalable, and flexible storage solutions for business-critical (virtual or physical) deployments. Windows Server 2012 delivers sophisticated storage virtualization capabilities, which enables you to use cost-effective industry-standard storage, for single-node and scalable multi-node deployments

Storage Spaces delivers storage virtualization capabilities within Windows Server 2012. The storage stack has been fundamentally enhanced to incorporate two new abstractions:

- Storage pools are administrative units of physical disks. Pools permit storage aggregation, elastic capacity expansion, and delegated administration.
- Storage spaces are virtual disks with associated attributes such as a desired level of resiliency, thin or fixed provisioning, automatic or controlled allocation on heterogeneous storage media, and precise administrative control.

Storage Spaces is completely integrated with failover clustering for high availability, and it is integrated with CSV for scale-out deployments. Storage Spaces includes the following features:

1. **Storage pools**. Storage pools are the fundamental building blocks for Storage Spaces. You can flexibly create storage pools based on the needs of the deployment. For example, given a set of physical disks, you can create one pool (by using all the available physical disks) or multiple pools (by dividing the physical disks as required). Furthermore, to maximize the value from storage hardware, you can map a storage pool to combinations of hard disks as well as solid-state drives (SSDs). Pools can be expanded dynamically by simply adding drives.
2. **Multitenancy**. Administration of storage pools can be controlled through access control lists (ACLs) and delegated on a per-pool basis, supporting hosting scenarios that require tenant isolation. Storage Spaces follows the familiar Windows security model; therefore, it can be fully integrated with Active Directory Domain Services.
3. **Resilient storage**. Storage Spaces support two optional resiliency modes: mirroring and parity. Per-pool support for disks that are reserved for replacing failed disks (hot spares), background scrubbing, and intelligent error correction allow continuous service availability

despite storage component failures. Note that only the mirroring option is available when deploying resiliency to cluster shared volumes.

4. **Continuous availability**. Storage Spaces is fully integrated with failover clustering, which allows it to deliver continuously available service deployments. One or more pools can be clustered across multiple nodes within a single cluster. Storage spaces can then be instantiated on individual nodes, and the storage will seamlessly fail over to a different node when necessary (in response to failure conditions or due to load balancing). Integration with CSVs permits scale-out access to data.
5. Optimal storage use. Server consolidation often results in multiple data sets sharing the same storage hardware. Storage Spaces supports thin provisioning to allow businesses to easily share storage capacity among multiple unrelated data sets and thereby maximize capacity use. Trim support permits capacity reclamation when possible.

   Storage Spaces is the ideal cost-effective solution for cloud infrastructures that are designed to support a generic population of virtual workloads that do not require specialized storage requirements or exceptional IOPS.

Data Deduplication

Data deduplication can yield significant storage cost savings in virtualized environments. Some common considerations are performance implications during the deduplication cycle and achieving maximum efficiency by locating similar data types on the same volume or LUN. Data deduplication can be carried out at the SAN level, or if you are using SAS storage with Storage Spaces, you can use the new Windows Server 2012 built-in deduplication feature.

Windows Server 2012 includes the following data duplication features that you can take advantage of in your cloud storage design:

- **Capacity optimization**. Data deduplication in Windows Server 2012 stores more data in less physical space. It achieves greater storage efficiency than was possible in previous releases with single-instance storage (SIS) or NTFS compression: data deduplication that can deliver optimization ratios of 2:1 for general file servers and up to 20:1 for virtualization data.
- **Scale and performance**. Windows Server 2012 data deduplication can run on dozens of large volumes of primary data simultaneously without affecting other workloads on the server. Low impact on the server workloads is maintained by throttling of CPU and memory resources consumed. You also have the option to set times when data deduplication should run, specify the resources available to it, and establish policies on file selection.
- **Reliability and data integrity**. When data deduplication is applied, it is essential to maintain data integrity. Windows Server 2012 takes advantage of checksum, consistency, and identity validation to ensure data integrity. Windows Server 2012 data deduplication also maintains redundancy to ensure that the data is recoverable in the event of data corruption.

Note that data deduplication is a feature that potentially will process all of the data on a selected volume, so careful planning should be done to determine if a server and attached volumes are suitable candidates for deduplication prior to enabling the feature. We strongly advise that during deployment of deduplication, you make regular backups of important data.

Note

Windows Server 2012 data deduplication is not available on CSVs running on a highly available scale-out file server cluster.

Thin Provisioning

In private cloud virtualization environments, thin provisioning is a common practice. This allows efficient use of the available storage capacity. The LUN or Storage Spaces virtual disk and corresponding CSV can grow as needed, typically in an automated fashion. However, storage can become overprovisioned in this scenario, so careful management and capacity planning are critical. Because physical allocation of data within a thin-provisioned volume is done on demand, theoretically the volume size can be set to a very high value that can easily keep all application data and snapshot copies.

The unallocated space in the volume is not exclusively reserved for the volume itself; therefore, all other applications can benefit from the shared pool of unallocated storage. Additionally, the volume size limits when using deduplication should be taken into account because the maximum sizes depend on the storage controllers when using SAN-based storage solutions.

Sophisticated and costly storage solutions offer just-in-time allocations (also known as thin provisioning) and the ability to reclaim storage that is no longer needed (also known as trim). Windows Server 2012 integrates with these sophisticated storage solutions to enable organizations to get the most out of their storage infrastructures at no additional cost. You can maximize the benefits of sophisticated storage infrastructure that is accessed through Windows Server 2012.

Requirements for thin provisioning by Windows Server 2012 include:

- Storage infrastructure that complies with the certification that is required for Windows Server 2012
- Standards-compliant hardware for identification.

To confidently deploy sophisticated storage solutions that support just-in-time allocation, you need to know that you can provision additional capacity as needed. Windows Server 2012 identifies thinly provisioned virtual disks, provides standardized notifications when use thresholds are crossed, and provides a platform that enables applications to release storage when it is no longer needed.

When designing for thin provisioning in your cloud infrastructure, consider the following Windows Server 2012 capabilities:

- **Identification**. Windows Server 2012 uses a standardized method to detect and identify thinly provisioned virtual disks, thus enabling additional capabilities delivered by the storage stack that is provided in the operating system and through storage-management applications.
- **Notification**. When configured physical storage use thresholds are reached, Windows Server 2012 notifies the administrator through events, which helps you to take appropriate action as soon as possible. These events can also be used for automated actions by management applications, such as System Center.
- **Optimization**. Windows Server 2012 provides a new application programming interface (API) that lets applications return storage when it is no longer needed. NTFS issues trim

notifications in real time when appropriate. Additionally, trim notifications are issued as part of storage consolidation (optimization), which is performed regularly on a scheduled basis.

Note
Server consolidation often results in multiple data sets sharing the same storage hardware. Storage Spaces supports thin provisioning to allow you to easily share storage capacity among multiple unrelated data sets and thereby maximize capacity use. Trim support permits capacity reclamation when possible.

Volume Cloning

Volume cloning is another common practice in virtualization environments. This can be used for both host and virtual machine volumes to dramatically decrease host installation times and virtual machine provisioning times.

Rapid provisioning is a common feature for private cloud implementations. In these environments, the expectation is that end users or departmental administrators will deploy virtual machines. Because of this, the system needs to respond rapidly to provisioning requests, and must scale those requests to accept large numbers of simultaneous requests. Clone-based provisioning has several key advantages over traditional copy-based provisioning.

Volume Snapshot

SAN volume snapshot copies are a common method of providing a point-in-time, instantaneous backup of a SAN volume or LUN. These snapshot copies are typically block-level and only use storage capacity as blocks change on the originating volume. Some SANs provide tight integration with Hyper-V, integrating both the Hyper-V VSS Writer on hosts and volume snapshot copies on the SAN. This integration provides a comprehensive and high-performing backup and recovery solution.

Windows Server 2012 has the ability to create application-consistent snapshots of the server application data. In Windows Server 2012, this is accomplished using the VSS infrastructure. VSS for SMB file shares extends the VSS infrastructure to perform application-consistent shadow copies of data stored on remote SMB file shares for backup and restore purposes. In addition, VSS for SMB file shares enable backup applications to read the backup data directly from a shadow copy file share rather than involving the server application computer during the data transfer. Because this feature takes advantage of the existing VSS infrastructure, it is easy to integrate with existing VSS-aware backup software and VSS-aware applications, such as Hyper-V.

Storage Automation

One of the objectives of the Microsoft private cloud solution is to enable rapid provisioning and deprovisioning of virtual machines. Doing so on a large scale requires tight integration with the storage architecture, in addition to robust automation. Provisioning a new virtual machine on an already existing LUN is a simple operation. However, provisioning a new CSV LUN and adding it to a host cluster are relatively complicated tasks that should be automated.

Historically, many storage vendors have designed and implemented their own storage management systems, APIs, and command-line utilities. This has made it a challenge to use a common set of tools and scripts across heterogeneous storage solutions.

Windows Server 2012 enables storage management that is comprehensive and fully scriptable, and administrators can manage it remotely. A WMI-based interface provides a single mechanism through which to manage all storage, including non-Microsoft intelligent storage subsystems and virtualized local storage (known as Storage Spaces). Additionally, management applications can use a single Windows API to manage different storage types by using standards-based protocols such as Storage Management Initiative Specification (SMI-S).

Designing the Cloud Network Infrastructure

The demand for hosted cloud requires integrated protection, the ability to add virtual appliances, and the capability to adapt virtual networking to the data center infrastructure. One of the most important issues to consider while building your private cloud is to ensure that the networking infrastructure is able to provide security, high availability, high performance, predictability, and resiliency, together with the ability to adapt for future cloud requirements. These prerequisites should be provided not only on the virtual layer by taking advantage of the Hyper-V networking features, but also in the physical layer where the switches and routers are connected. Figure 2 shows a common private cloud infrastructure and different layers that must be covered during the design phase.

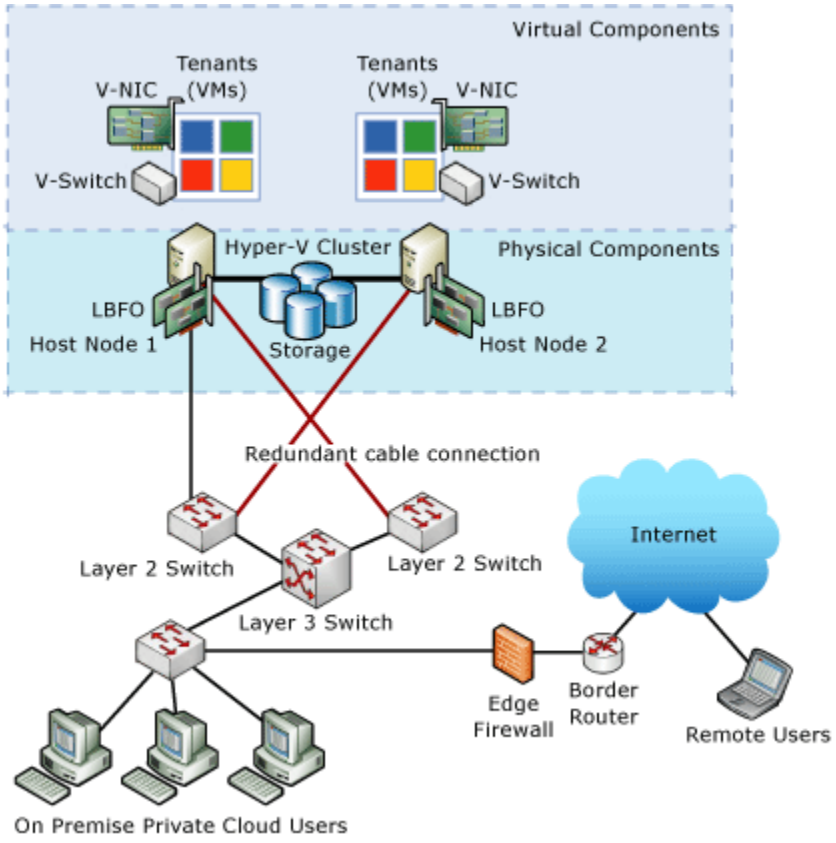

Figure 2. Network infrastructure overview

This section will cover the networking design considerations to assist you with building your cloud infrastructure.

Network Infrastructure

You must access your current network infrastructure and verify the network is capable of receiving the new set of servers that will be hosting your cloud infrastructure. As shown in Figure 2, there are virtual components and physical components. Because the physical components will be in place before the initial setup of the cloud infrastructure, it is important to review the following elements of your current network infrastructure:

Requirements	Description
Switches where the Hyper-V clusters will be connected	• Layer 2 or layer 3 switches that support major Windows Server 2012 networking features. • Ethernet 1 GB or 10 GB, Fibre Channel, or InfiBand.
Cabling system	• Use the cabling system that matches with your layer 1 technology (Ethernet, Fibre Channel, or InfiBand).
Router	• Border router to route traffic from the private cloud to the Internet.
Edge Firewall/Gateway	• A firewall/gateway that allows secure web access from private cloud to Internet and from remote users to the private cloud.

Note

For more information about InfiniBand technology see InfiniBand® Roadmap.

When designing network connectivity for a well-managed cloud infrastructure, the virtualization hosts should have the following specific networking requirements:

Requirements	Description
Support for 802.1q VLAN tagging	To provide network segmentation for the virtualization hosts, supporting management infrastructure, and workloads. This is one method you can use to help secure and isolate data traffic for a private cloud.
Remote out-of-band management capability	To monitor and manage servers remotely over

	the network regardless of whether the server is turned on or off.
Support for PXE version 2 or later	To facilitate automated physical server provisioning.
Support for ECN switches (RFC 3168 compliant)	To support Windows Server 2012 Datacenter TCP (DCTPC).
Support for 802.1az and 802.1Qbb (priority flow control)	To support Datacenter Bridging (DCB).
Network interfaces and virtual networking gateway that support GRE offload (NVGRE)	To support Windows Server 2012 Network Virtualization.

Before deploying a cloud infrastructure, you should also address the following requirements:

1. Address any network bottleneck prior to building the cloud infrastructure.

   Ensure that redundant components are working. For example, if a switch has two (or more) power supplies, perform a failover test to validate if it is properly working.
2. Make note of the results.
3. Document (or update the documentation) for the current network infrastructure.
4. Additionally, a cloud infrastructure should meet the following requirements to make sure that it is highly available and well-managed:
   - Multiple paths to the switches for redundancy. Should a switch fail this can provide resiliency in the provisioned switch. Consult the switch vendor for specific recommendations.
   - Redundant power supplies and cooling fans, to increase the number of faults the switches and routers can survive.

Traffic Flow Isolation

In a cloud infrastructure it is important that the traffic generated by each tenant is securely isolated from other tenants. The existing Windows Server 2008 Hyper-V Switch architecture does not allow a component outside the switch to add to the security and isolation that is already provided by the switch. The new Windows Server 2012 Hyper-V Extensible Switch has support for isolation policies as well as allowing for extensibility and lets third parties add in filters to provide their own forwarding rules.

Note

For more information about Hyper-V Virtual Switch, see Hyper-V Virtual Switch Overview

Another important feature that Windows Server 2012 Hyper-V introduces is called Network Virtualization. This feature removes the constraints of VLAN and hierarchical IP address assignment for virtual machine provisioning. In addition, network virtualization maintains the necessary multi-tenant isolation and security requirements. This feature introduces the concept of location-independent addressing by virtualizing the IP address. It creates virtual Layer-2/Layer-3

topologies over any physical network that supports bidirectional IP connectivity. This means that physical networks can be hierarchical three-tier networks, with full directional bandwidth, a Clos network, or a large Layer-2 infrastructure. The advantage is that virtual networks can dynamically be configured by software as virtual machines are added to the cloud, and it can span over multiple physical subnets and across multiple sites.

Windows Server 2012 Network Virtualization can support a larger number of network isolation groups than the 4,094 maximum provided by VLANs (per IEEE 802.1Q standard). With VLAN-based network isolation, all of the workloads in an isolation group must be on a single subnet. Network Virtualization also allows network isolation groups to be defined across network boundaries such as subnets. This improves flexibility by removing physical network configuration constraints in determining where workloads can be placed.

Note

For more information about Hyper-V Network Virtualization see Hyper-V Network Virtualization Overview.

Enterprises that already have a large Fibre Channel SAN installation for storage service but want to migrate away from additional investment in the Fibre Channel technology will be able to use data center bridging (DCB) to build an Ethernet-based converged fabric for both storage and data networking. Having a unified Ethernet fabric can reduce the future TCO and simplify the management. For enterprises who have already adopted, or who plan to adopt iSCSI as their storage solution, DCB can also provide hardware-assisted bandwidth reservation for iSCSI traffic to ensure performance isolation. DCB-capable Ethernet network adapters must be installed in computers that are providing Windows Server 2012 DCB, and DCB-capable hardware switches must be deployed on the network that will host the cloud infrastructure.

The following table summarizes the design requirements for traffic isolation and the Windows Server 2012 feature that should be used to accomplish this:

Design requirements	Windows Server 2012 feature	How does it help?
Separate workloads from internal IP addresses per tenant	Hyper-V Network Virtualization	You can separate workloads from internal IP addresses in order to minimize configuration changes that are necessary for IP addresses, Domain Name System (DNS), and other virtual machine configurations.
Separate server and network administrator duties to allow operational isolation		You can simplify management since migration and placement of workloads are independent from the underlying physical network configuration.
Provide isolation beyond		Using software based policy in

VLAN configuration		conjunction with policy-based data center networks makes it possible to implement isolation without using VLANs.
Migrate servers across data centers in a flexible way while traffic is isolated from other tenants		You can use flexible workload placement while keeping the current IP address schema as it is not limited to a physical IP subnet or VLAN configuration.
Optimize server and network utilization to not affect other tenants		By removing the dependency of virtual machine placement based on physical network infrastructure you will increase the flexibility for workload placement and improve the overall server and network utilization.
Automate management and deployment		By using the Network Virtualization PowerShell cmdlet it is possible to accomplish this design requirement.
Allow lower-level traffic inspection with rules that can be applied per tenant	Hyper-V Switch Extensibility	Filtering extensions can inspect, drop, modify, and insert packets.
Allow different tenants to implement different filters according to their traffic-isolation needs		Extensions plug in to each instance of a vSwitch on a machine, and those extensions are either filters or Windows Filtering Platform (WFP) providers.
Monitor tenant traffic without modifying the existing vSwitch traffic		Capture extensions can inspect traffic and generate new traffic for reporting purposes. Capture extensions do not modify existing vSwitch traffic.

Another mechanism that can be used to assist traffic isolation between virtual machines in Windows Server 2012 is new support for Hyper-V switch port ACLs. This feature will be covered in more detail in the Security Considerations next section of this document.

Security Considerations

Considering what was mentioned previously in the section Cloud Architecture Considerations, security is considered to be a wrapper around the entirety of the solution. When designing network connectivity for a secure cloud infrastructure, there are a series of security considerations for the current physical network infrastructure that must be verified before deploying the cloud infrastructure.

The first recommended step is to perform a network vulnerability assessment (NVA) in the current infrastructure. Before securing the assets you must evaluate what's in place via an analytical assessment of every control point on the network (such as switches and routers). When performing an NVA it is important to follow a core framework that must include at least the following items:

Task	Example
Detect and document the vulnerabilities	• Description: Switches located in the data center do not have the latest firmware and are vulnerable to Internet Control Message Protocol (ICMP) Redirect Attack.
Assign risk levels to discovered vulnerabilities	• Criticality: Severe • Reason: If an attack successfully exploits the vulnerabilities on the switches located in the data center, they could redirect the traffic and disrupt traffic flow, causing major downtime for the hosts connected to that switch.
Identify vulnerabilities that have not been remediated and take actions to remediate	• Description: Two months ago the NVA Report 00001 detected that switches located in the data center were vulnerable to ICMP Redirect Attack. The problem was not fixed. • Action: Escalate the problem to upper management to address this issue immediately.

It is important to perform the NVA on the current network infrastructure because an attacker usually looks for poorly configured network devices to exploit. Besides the vulnerabilities that are resolved by applying updates the come from the device vendor, there are other vulnerabilities that need to be addressed, such as those caused by insecure administration practices, such as weak default installation settings (including weak password) and wide-open access controls (no ACLs). The following include some of the main network threats:

- Sniffing
- Spoofing

- Session hijacking
- Denial of service

Cloud operators and private cloud network administrators must have knowledge of the threats that can affect the network infrastructure in order to apply effective countermeasures.

Note

For more information about Network Security, see Advanced Network Security.

Once the current physical network infrastructure is secured, the next phase is to plan how to extend this security to the virtual network while allowing the traffic between physical and virtual to flow in a secure manner. Security considerations while designing and planning the cloud infrastructure should also include:

- Secure access control between virtual machines (on the same host or in different hosts)
- Traffic control to avoid tenants overloading the network
- Avoiding rogue IP distribution
- Ensure network availability and performance

Secure Access Control

Windows Server 2012 supports Hyper-V port ACLs that are enforced by the Hyper-V virtual switch. These ACLs are fine-grained rules that can either allow or deny traffic destined to or from a virtual machine's virtual network adapter. ACL filters are based on the IP address, IP address prefix, or the MAC address of the incoming or outgoing packets.

Since ACLs are a port property of the Hyper-V virtual switch, when a virtual machine live migrates to another host, the ACLs move with the virtual machine. Although it is technically possible to provide multi-tenancy isolation by using only ACLs, the challenge is managing and keeping all ACLs updated. For this reason, ACLs are intended to ensure that virtual machines do not spoof their IP or MAC addresses or to control specific network traffic for particular address ranges.

Consider developing an access control plan that describes a method to establish a secure and usable environment. A typical access control plan might include the following sections:

- Security goals: define the resources and processes that you are protecting.
- Security risks: enumerate the types of security hazards that affect your enterprise, including what poses the threats and how significant these threats are.
- Security strategies: describe the general security strategies necessary to meet the threats and mitigate the risks.
- Security policy: policy to define and enforce your security strategy on any number of virtual machines.
- Information security strategies: define how you plan to implement information security solutions.
- Administrative policies: document policies for delegation of administrative tasks and monitoring of audit logs to detect suspicious activity.

Note

For more information about Access Control List on Hyper-V see Hyper-V Virtual Switch Overview.

Traffic Control

As documented in the Cloud Security Challenges Secondary to Cloud Essential Characteristics document, one of the concerns as a designer of a private cloud solution is that: "A rogue application, client, or DoS attack might destabilize the data center by requesting a large amount of resources. How do I balance the requirement that individual consumers/tenants have the perception of infinite capacity with the reality of limited shared resources?"

One way to address this concern is by controlling the network traffic. QoS in Windows Server 2012 is designed to help manage network traffic on the physical network and on the virtual network. Policy-based QoS is designed to manage network on the physical network. In addition, a new functionality in QoS, referred to as Hyper-V QoS, is designed to manage traffic at the virtual switch level.

The use of policy-based QoS allows cloud operators to specify network bandwidth control based on application type, users, and computers. Policy-based QoS can also be used to help control bandwidth costs and negotiate service levels with bandwidth providers or departments (tenants). Hyper-V QoS enables cloud operators to guarantee specific performance levels based on service level agreements (SLAs). Hyper-V QoS helps ensure that no tenant is impacted or compromised by other tenants on their shared infrastructure, which includes computing, storage, and network resources.

Consider developing a QoS plan that describes how to establish a secure a usable environment. A typical QoS plan might include the following sections:

- SLA: plan QoS policy based on the tenants' SLA.
- Network utilization: gauge network utilization to understand traffic flow and how QoS can be used to optimize performance.
- Policy enforcement: enforce QoS policies on Single Root I/O Virtualization (SR-IOV) network adapters that support bandwidth reservation per virtual port.

These sections should be considered per tenant because it is possible to create multiple virtual network adapters in Hyper-V and specify QoS on each virtual network adapter individually.

Note

For more information about Policy Based QoS see Quality of Service (QoS) Overview.

Avoid Rogue IP Distribution

The same core concern that a rogue application, client, or denial of service (DoS) attack might destabilize the data center, mentioned previously, also applies in this case. If a rogue Dynamic Host Configuration Protocol (DHCP) server is capable of providing IP addresses to computers in the tenant network, these computers might lose access to resources and disrupt the whole tenant network infrastructure.

The DHCP server role in Windows Server 2012 introduces a new policy-based IP address and option assignment feature. With the Policy Based Assignment (PBA) feature the cloud operator will be able to group DHCP clients by specific attributes based on fields contained in the DHCP client request packet. This feature allows a greater control of configuration parameters delivered to network devices.

A typical DHCP PBA plan might include the following sections:

- Define conditions: DHCP PBA can be defined according to fields in the DHCP client request. Define which condition better fits on your cloud infrastructure network.
- IP scope: define the DHCP IP scope that will be used for the tenants.
- Lease duration: define the DHCP lease duration for each tenant network.
- Additional options: define the DHCP scope or server options that will be provided to the tenants. If policies exist at the server and scope levels, the server applies both sets of policies and evaluates the scope policies before the server policies. The processing order for a scope-level policy defines the order of evaluation within the scope.

Note

For more information about DHCP PBA see Step-by-Step: Configure DHCP Using Policy-based Assignment.

Scalability and Performance Considerations

Many network architectures include a tiered design with three or more tiers such as core, distribution, and access. When designing a cloud infrastructure the current network infrastructure should be evaluated to understand the port bandwidth and quantity required at all layers, in addition to the ability of the distribution and core tiers to provide higher-speed uplinks to aggregate traffic. Additional considerations include Ethernet broadcast boundaries and limitations, and spanning tree and/or other loop avoidance technologies should be considered.

Physical separation of the networks should also be considered in order to provide another layer of isolation and security and increase the overall performance per segment. When designing a cloud infrastructure ensure that the servers that will be used to host the virtual machines support different traffic profiles by either using separate physical adapters for each traffic type, or by using VLAN tagging or virtual NICs. The table below describes a cloud infrastructure model with five physical network segments:

Traffic	Description
Management	Network that handles all the management traffic. This traffic will be from the host to the management workstation. Cloud operators will connect to the host system to manage the cloud infrastructure.
Cluster	Network dedicated to cluster communications.

Storage	Handle all the storage traffic in scenarios where you use Ethernet-based storage protocols.
Live migration	Responsible for handling the live migration traffic that will take place from one host to another.
Tenant	Network dedicated to tenant traffic. An additional layer of isolation within the tenant network can be provided by using VLAN IDs in the virtual switch.

Note

It is also possible to route all these traffic profiles through a single or teamed 10 GB network adapter. This converged networking model reduces the number of network adapters and cabling required for your private cloud infrastructure.

If business requirements dictate that your cloud infrastructure should have five physical network segments, the same layout can be applied to the virtual network infrastructure. When implementing those requirements it is also important to create a standard nomenclature for the network adapters names in order to reflect which network they are connected to. This not only helps to easily identify the network but also to create a standard for future automations via Windows PowerShell.

Although physical separation of the traffic can be a business requirement, there will be scenarios that this is not the case and the main business requirement is to reduce implementation cost while maintaining security isolation between tenants. When the business requirements lead you to this design decision you can converge all the data center networks into basically two networks, physically isolated: a data center network can carry all the storage, live migration, clustering, and management traffic flows, and a second network can carry all of the virtual machine tenant-generated traffic. You can still apply QoS policies to guarantee minimum traffic for each flow and use VLAN ID in the virtual switch to isolate the traffic within the tenant network.

When choosing the networking hardware for your cloud infrastructure, consider the following options:

Network technology	Advantages	Disadvantages
10 GB Ethernet	• Great performance • Offers QoS (DCB) and flexible bandwidth allocation • New hardware offloads available	• RDMA optional (for SMB 3.0 file access) • Physical switch ports more expensive
InfiniBand (32 GB and 56	• Very high performance,	• Network management

GB)	low latency • RDMA included (for SMB 3.0 file access)	different than Ethernet • More expensive to implement
1 GB Ethernet	• Adequate performance for many workloads	• Not very scalable

Remote interfaces and management of the network infrastructure via Secure Shell (SSH) or similar protocol is important to both automation and resiliency of the data center network. Remote access and administration protocols can be used by management systems to automate complex or error prone configuration activities. For example, adding a VLAN to a distributed set of access-tier switches can be automated to avoid the potential for human error.

Host and Virtualization Design

There are a number of critical design decisions you need to make that apply to your virtualization infrastructure. Hardware virtualization uses software to create a virtual machine that emulates a physical computer. This creates a separate operating system environment that is logically isolated from the host server. By providing multiple virtual machines at once, this approach allows several operating systems to run simultaneously on a single physical machine.

Windows Server 2012 Hyper-V technology is based on a 64-bit hypervisor-based microkernel architecture that enables standard services and resources to create, manage, and execute virtual machines with the cloud infrastructure. The Windows Hypervisor runs directly above the hardware and ensures strong isolation between the partitions by enforcing access policies for critical system resources such as memory and processors. The Windows Hypervisor does not contain any third-party device drivers or code, which minimizes its attack surface and provides a more secure architecture.

In addition to the Windows Hypervisor, there are two other major elements to consider with Hyper-V: a parent partition and child partition. The parent partition is a special virtual machine that runs Windows Server 2012, controls the creation and management of child partitions, and maintains direct access to hardware resources. In this model, device drivers for physical devices are installed in the parent partition. In contrast, the role of a child partition is to provide a virtual machine environment for the installation and execution of guest operating systems and applications.

Windows Server 2012 Hyper-V Host Design

There are many important considerations you need to make when designing the Windows Server 2012 host and Hyper-V components as part of your cloud infrastructure. In this section we will discuss decision points regarding:

- Licensing
- Operating system configuration
- Memory and Hyper-V Dynamic Memory

- Storage adapters
- Hyper-V host failover design
- Hyper-V guest virtual machine design

Licensing

Different versions of Windows Server 2012 include different virtualization rights, which is the right and license to run a specified number of virtual machines based on Windows. For a private cloud environment, you will want to use Windows Server 2012 Datacenter Edition.

Operating System Configuration

The following outlines the general considerations for the Hyper-V Host Operating system. Note that these are not meant to be installation instructions but rather the process requirements and order.

To install and use the Hyper-V role, you will need the following:

- An x64-based processor
- Hardware-assisted virtualization support in the processor and BIOS
- Hardware-enforced data execution prevention (DEP) support in the processor and BIOS
- Use the latest hardware device drivers and system BIOS updates
- Hyper-V parent partition operating system must be domain-joined. This is required to support failover clustering and other management capabilities.
- Hyper-V server roles and failover clustering features. Failover clustering will provide high availability so that virtual machines remain available even if a member of the cluster is disabled.
- Apply relevant Windows updates, including out-of-band (OOB) updates not offered on Microsoft Update
- All nodes, networks, and storage must pass the Cluster Validation Wizard

Please see Hyper-V Overview for more information on hardware and software requirements.

Memory and Hyper-V Dynamic Memory Options

Dynamic Memory, introduced in Windows Server 2008 R2 Service Pack 1 (SP1), defined startup memory as the minimum amount of memory that a virtual machine can have. However, Windows requires more memory during startup than the steady state. As a result, administrators sometimes assign extra memory to a virtual machine because Hyper-V cannot reclaim memory from these virtual machines after startup. In Windows Server 2012, Dynamic Memory introduces a minimum memory setting, which allows Hyper-V to reclaim the unused memory from the virtual machines. This is reflected as increased virtual machine consolidation numbers.

Windows Server 2012 also introduces Smart Paging for reliable virtual machine restart operations. Although minimum memory increases virtual machine consolidation numbers, it also brings a challenge. If a virtual machine has a smaller amount of memory than its startup memory and it is restarted,

Hyper-V needs additional memory to restart the virtual machine. Due to host memory pressure or virtual machine states, Hyper-V might not always have additional memory available. This can cause sporadic virtual machine restart failures. Smart Paging is used to bridge the memory gap between minimum memory and startup memory, and allow virtual machines to restart reliably.

For more information regarding Dynamic Memory, please see Hyper-V Dynamic Memory Overview.

In addition to the general guidance above, specific applications or workloads, particularly those with built-in memory management capabilities, such as SQL Server or Exchange Server, might provide workload-specific guidance. An example of such guidance is Running SQL Server with Hyper-V Dynamic Memory.

When designing for memory requirements for host servers in the Hyper-V cluster, you should consider how many virtual machines you want to support on each server. Windows Server 2012 supports up to 4 TB of memory for the host operating system and up to 1 TB for each virtual machine.

One approach you can take is to consider how many virtual machines you wish to support of each service class you plan to offer in your private cloud. For example, you may want to support up to 10 virtual machines on each host system in the cluster. You also want to offer the following service classes in terms of amount of memory offered:

- **Bronze** – 1 GB of RAM for the virtual machine
- **Silver** – 4 GB of RAM for the virtual machine
- **Gold** – 16 GB of RAM for the virtual machine

You estimate that consumers of your private cloud will acquire these service offerings in the following percentages:

- **Bronze** – 30%
- **Silver** – 60%
- **Gold** – 10%

You can compute the amount of RAM required in each host in this example using the following:

(1GBx3) + (4GBx6) + (16GBx1) + 2GB (for the host OS) = 45 GB

Storage Adapters

Design decisions regarding storage adapters on the Hyper-V private cloud host are important. The type of storage adapter you choose will determine the speed, latency, reliability, performance, and cost of your cloud infrastructure storage components. In this section we will discuss:

- MPIO configuration
- Performance settings
- Network adapter teaming configurations

MPIO Configuration

As discussed earlier, Microsoft MPIO architecture supports iSCSI, Fibre Channel, and SAS SAN connectivity by establishing multiple sessions or connections to the storage array.

Performance Options

The following Hyper-V network performance improvements should be tested and considered for production use (note that many of these technologies require hardware support):

- **Transmission Control Protocol (TCP) checksum offload** benefits both CPU and overall network throughput performance, and it is fully supported by live migration.
- **Jumbo frames** capability is extended to virtual machines with Windows Server 2012 Hyper-V. Just as in physical network scenarios, jumbo frames add the same basic performance enhancements to virtual networking. That includes up to six times larger payloads per packet, which improves overall throughput and also reduces CPU utilization for large file transfers. For more information on jumbo frames, please see Hyper-V Networking Options – Jumbo Frames.
- **Dynamic Virtual Machine Queue (DVMQ)** enables you to span processing of virtual machine network traffic across all processors in the host operating system. This feature enables you to scale up and scale down the CPU utilization based on demand.
- **Scale and resiliency.** The computer that runs Hyper-V can be configured with up to 320 logical processors and 4 TB of memory. Virtual machines can be configured with 32 virtual processors and 1 TB of memory. Improved handling of hardware errors increases the resiliency and stability of the virtualization environment. For more information on scale and resiliency features, please see Hyper-V Support for Scaling Up and Scaling Out Overview.
- **Single root I/O virtualization (SR-IOV).** Use of SR-IOV maximizes network throughput while minimizing network latency, in addition to the CPU overhead required for processing network traffic. SR-IOV bypasses the virtual switch stack and enables the virtual machine direct access to the hardware. Network adapter and BIOS support is required. For more information on SR-IOV please see Hyper-V Support for Scaling Up and Scaling Out Technical Preview.
- **New .VDHX disk format.** The new format increases the maximum storage size per virtual hard disk, and improves the stability and efficiency of those disks. The new VDHX disk format supports up to 64 TB of storage and supports newer 4K disk architecture. It also provides built-in protection from corruption stemming from power failures and prevents performance degradation on some large-sector physical disks. For more information on the new VHDX disk format, please see Hyper-V Virtual Hard Disk Format Technical Preview.
- **Virtual non-uniform memory access (NUMA).** Newer operating systems and high-performance applications such as SQL Server include optimizations that recognize a computer's NUMA topology to increase performance by considering NUMA when scheduling threads or allocating memory. The virtual NUMA feature makes it possible for the guest operating system and NUMA-aware applications running in the virtual machine (such as SQL Server) to take advantage of these performance optimizations. A virtual NUMA topology is projected to the guest operating system. The default virtual NUMA topology is optimized to match the NUMA topology of the physical computer. Note that if a virtual machine uses dynamic memory, then a flat NUMA topology is reflected to that VM. In addition, in Windows Server 2012 failover clustering, NUMA topology of members of the cluster is taken into consideration when automated decisions are made to move virtual machines.

- **Hyper-V Offloaded Data Transfer.** To take advantage of innovations in storage hardware that provide near-instantaneous copying of large amounts of data, Hyper-V in Windows Server 2012 introduces Offloaded Data Transfer (ODX). With this new feature, Hyper-V workloads use the offload semantics of the host hardware, in addition to the virtual storage stack, to perform certain internal operations on virtual hard disks that require large amounts of data to be copied. Hyper-V performs these operations faster than was previously possible. For more information on Windows Server 2012 ODX, please see Hyper-V Offloaded Data Transfer Overview.

Network Adapter Teaming Configurations

Network adapter teaming can be utilized to enable multiple redundant network adapters and connections between servers and access-tier network switches. Teaming can be enabled via hardware or software-based approaches. Windows Server 2012 includes built-in support for network adapter teaming via the new load balancing and failover (LBFO) feature, where any two network adapters can be teamed, regardless of make, model, or speed. Teaming can enable multiple scenarios including path redundancy, failover, and load-balancing.

Windows Server 2012 LBFO (Load Balancing and Failover, also known as NIC Teaming), allows multiple network adapters on a computer to be placed into a team for the following purposes:

- Bandwidth aggregation
- Traffic failover to prevent connectivity loss in the event of a network component failure

Note

Windows Server 2012 NIC Teaming enables you to configure the team in ways that can have all adapters active or reserve some adapters for standby. We recommend that you use the all active configuration for your private cloud NIC teams.

This feature has been a requirement for independent hardware vendors (IHVs) to enter the server network adapter market, but until now network adapter teaming has not been included in Windows Server operating systems. NIC Teaming enables you to team network adapters of different speeds and from different manufacturers.

Note

It is recommended that you do not team network adapters of different speeds. The reason for this is that while it is a supported configuration, if the higher speed adapter fails, performance on the slower adapter will be severely impacted.

It is recommended that you do not team network adapters of different speeds. The reason for this is that while it is a supported configuration, if the higher speed adapter fails, performance on the slower adapter will be severely impacted.

Network adapter teaming in Windows Server 2012 also works within a virtual machine. This allows a virtual machine to have virtual network adapters that are connected to more than one Hyper-V switch and still have connectivity even if the network adapter under that switch gets disconnected. This is particularly important when working with features such as SR-IOV because SR-IOV traffic does not go through the Hyper-V switch. Thus, it cannot be protected by a team that is under a Hyper-V switch. With the virtual machine teaming option, an administrator can set

up two Hyper-V switches, each connected to its own SR-IOV-capable network adapter. At that point:

- Each virtual machine can then install a virtual function from one or both SR-IOV network adapters. Then, in the event of a network adapter disconnect, the virtual machine can fail over from the primary virtual function to the backup virtual function.
- Alternately, the virtual machine might have a virtual function from one network adapter and a non-virtual function network adapter from the other switch. If the network adapter that is associated with the virtual function gets disconnected, the traffic can fail over to the other switch without loss of connectivity.

Note
NIC Teaming is compatible with all networking capabilities in Windows Server 2012 with three exceptions:

- SR-IOV
- RDMA
- TCP Chimney (TCP Chimney is disabled by default in Windows Server 2012)

For SR-IOV and RDMA, data is delivered directly to the network adapter without passing through the virtual networking stack. Therefore, it is not possible for the network adapter team to look at or redirect the data to another path in the team. In addition, TCP Chimney is not supported with network adapter teaming in Windows Server 2012. Network adapter teaming requires the presence of at least one Ethernet network adapter, which can be used for separation of traffic using VLANs. All modes that provide fault protection through failover require at least two Ethernet network adapters. The Windows Server 2012 implementation supports up to 32 network adapters in a team.

For more information on Windows Server 2012 load balancing and failover, please see Load Balancing and Failover Overview.

Dedicated Compute and Storage Clusters Using SMB 3.0 and Windows Server 2012 File Server

In this design pattern, the Hyper-V cluster providing the compute component for the cloud infrastructure is separate from the storage cluster. When you separate the compute from the storage cluster, you have the opportunity to scale compute capacity and storage capacity separately. This provides you more flexibility when designing your scale units for compute and storage. In this pattern, two 10 GbE adapters on the compute cluster are teamed which support management, cluster, live migration, and storage traffic. The Windows Server 2012 storage cluster is also configured with teamed 10 GbE adapters and hosts VHDX and configuration files that are accessed through SMB 3.0 file shares over the network. The storage configuration on the storage cluster can connect to any type of block storage solution.

Hyper-V Host Failover Cluster Design

A Hyper-V host failover cluster is a group of independent servers that work together to increase the availability of applications and services. The clustered servers (called nodes) are connected by physical cables and by software. If one of the cluster nodes fails, another node begins to

provide service (a process known as failover). In case of a planned migration (called live migration), users experience no perceptible service interruption.

The host servers are one of the critical components of a dynamic, virtual infrastructure. Consolidation of multiple workloads onto the host servers requires that those servers be highly available. Windows Server 2012 provides advances in failover clustering that enable high availability and live migration of virtual machines between physical nodes. Some of the new features which you will need to include in your private cloud design decisions for host cluster members include:

- Cluster scalability features
- CSVs
- Support for scale-out file servers
- Cluster-aware updating
- Virtual machine application monitoring
- Cluster validation tests
- Active Directory Domain Services integration
- Multisite support
- Cluster upgrade and migration
- iSCSI software target integration
- Windows PowerShell support

For more information on each of these features and how they can fit into your cloud infrastructure design, please see What's New in Failover Clustering.

Private Cloud Infrastructure without Failover Clustering

It is important to note that a private cloud infrastructure does not require failover clustering. Failover clustering provides high availability for stateful applications that are not specifically designed to work on and support cloud capabilities. Specific cloud capabilities are targeted at the stateless applications of the future.

Prior to Windows Server 2012, Live Migration of virtual machines from one host to another required failover clustering; thus a failover cluster defined the scope of virtual machine and workload mobility. However, Windows Server 2012 introduces what is known as the "shared nothing" Live Migration feature.

Shared nothing Live Migration enables the cloud service provider to move virtual machines from one Hyper-V host to another without requiring failover clustering or shared storage. With only a network cable (or even wireless connection) the virtual machine and its virtual disk and configuration files can be moved from one machine to another. Private cloud service providers could take advantage of this capability to run virtual machines hosting stateless workloads and place virtual machines on specific hosts based on their fabric controller of choice.

This design guide focuses on implementing failover clustering in the private cloud infrastructure because the Windows Server 2012 failover clustering feature adds many vital capabilities for the management, monitoring and control of the overall cloud solution and is tightly integrated with Windows Server 2012 Hyper-V technologies. In addition, we believe that, for at least the near

term that stateful applications will represent the most common workload running in a private cloud.

Host Failover Cluster Topology

In a Microsoft Private Cloud infrastructure, we recommend two standard design patterns. The server topology should consist of at least two Hyper-V host clusters. The first should have at least two nodes, and will be referred to as the management cluster. The second, and any additional clusters, will be referred to as fabric host clusters. The second cluster might be the compute cluster, and the third cluster might be the storage cluster. Alternatively, the second cluster can be a combined computer and storage cluster that is either symmetric or asymmetric.

Note

In the current context, a symmetric cluster is a cluster where each member of the cluster is directly attached to storage. Conversely, an asymmetric cluster has some members attached to storage and others unattached to storage. Typically, the unattached cluster members are performing the compute function (actually running the virtual machines) and the attached members of the cluster are acting as scale-out file servers that host the virtual machine files for the compute nodes.

In some cases such as smaller-scale scenarios or specialized solutions, the management and fabric clusters can be consolidated onto the fabric host cluster. Special care has to be taken in that case to ensure resource availability for the virtual machines that host the various parts of the management stack. There are significant security issues with this design, so assiduous attention to traditional and cloud-based security measures is mandatory.

Each host cluster can contain up to 64 nodes. However, for file server clusters running the Windows Server 2012 scale-out file server role that host VHDX files used by the computer cluster, there is an informal 8-node limitation. The compute cluster can host its own storage, or can use SMB 3.0 file based storage to access storage on the file server cluster.

Note

The 8-node informal limitation is based on what has been tested as of the writing of this document. You can exceed the 8-node limitation and customer support services will work with you in identifying and resolving issues should they arise.

Compute Cluster Traffic Profiles

A variety of host cluster traffic profiles or types are used in a Hyper-V failover cluster. The network requirements to support these traffic types enable high availability and high performance.

The Microsoft cloud infrastructure configurations support the following Ethernet traffic profiles:

- **Management network traffic.** The management network is required so that hosts can be managed to avoid competition with guest and other infrastructure traffic needs. The management network provides a degree of separation for security and ease of management purposes. This network is used for remote administration of the host, communication to management systems (System Center agents), and other administrative tasks.

- **iSCSI, Fibre Channel over Ethernet, or SMB 3.0 traffic (Storage Traffic)**. If using iSCSI, FCoE, or SMB 3.0, the iSCSI, FCoE, or SMB 3.0 network is configured so that storage traffic is not in contention with any other infrastructure or tenant traffic. For all these storage connections, an MPIO configuration with two independent physical ports is required. In the case of SMB 3.0 access to file storage, multiple network adapters can be used in conjunction with SMB multichannel and transparent failover to provide benefits similar to MPIO.
- **CSV/cluster communication traffic.** Usually, when the cluster coordinator node that "owns" a virtual hard disk (VHD) file in CSV performs disk I/O, the node communicates directly with the storage devices; for example, through a SAN. However, storage connectivity failures and other non-failure scenarios sometimes prevent a given node from communicating directly with the storage device. To maintain functionality until the failure is corrected, the node redirects the disk I/O through a cluster network (the preferred network for CSV) to the node where the disk is currently mounted. This is called CSV redirected I/O mode.
- **Live migration traffic.** During live migration, the contents of the memory of the virtual machine running on the source node needs to be transferred to the destination node over a LAN connection. Large virtual machines can consume many gigabytes of memory that need to be transferred over the network. To provide a high-speed transfer, a dedicated, redundant, 10 Gbps live migration network is required. This significantly reduces the time required to evacuate the virtual machines off a host with zero downtime during maintenance or Windows updates. The time it takes to complete an evacuation of a cluster member depends on the total amount of memory consumed by running virtual machines on that system and the amount of bandwidth available on the Live Migration network.
- **Tenant traffic.** Tenant traffic is dedicated to virtual machine LAN traffic. The tenant traffic can use two or more 1 GB or 10 GB networks using network adapter teaming, or virtual networks created from shared network adapters. You can implement one or more dedicated virtual machine networks. The amount of bandwidth required on the tenant network may be less than what you require on any of the infrastructure networks, depending on the type of workloads you expect to support on your private cloud. One way to determine the bandwidth you want to make available on your tenant network is to define your network service classes and then determine what is the total amount of bandwidth required for you to meet the SLA for your network bandwidth defined service classes for all VMs running on your host.

When you look at each of the traffic profiles presented here, you can categorize each of them into one of two categories:

- Private cloud infrastructure traffic
- Private cloud tenant traffic

Private cloud infrastructure traffic includes management, storage, CSV/cluster and Live Migration traffic. Tenant traffic is defined by traffic to and from virtual machines running within the private cloud infrastructure.

Note

There are some security considerations that you need to address which extend past the isolation methods we've talked about until now. While you can use Hyper-V virtual switch port ACLs and VLAN tagging and even private VLANs to obtain a good degree of separation between host and guest traffic, you may want to introduce additional security

for your Live Migration traffic. During the process of a Live Migration, tenant data, by default, is moving unencrypted over the Live Migration network. There is a reasonable chance that this data contains private information that might be of interest to intruders. If the physical or logical infrastructure of the Live Migration network were to be compromised, the Live Migration traffic could be accessible in an unencrypted format to the intruder. Because of this, we recommend that you use IPsec to secure the connections between hosts on the Live Migration network.

There are several options available regarding how you manage these traffic profiles so that they receive the bandwidth they require while enforcing separation between the tenant traffic and the cloud infrastructure traffic (management, storage, CSV/cluster, and live migration). These are:

- **Dedicated network adapters for each traffic profile.** This is a traditional approach that was recommended for Windows Server 2008 R2 Hyper-V clusters. With new features included in Windows Server 2012, this is no longer considered the preferred design. However, it simplifies upgrading the current Windows Server 2008 R2 to a Windows Server 2012 infrastructure.
- **Dedicated network adapters for cloud infrastructure traffic and tenant traffic.** In this design pattern, separate adapters and networks are used for the cloud infrastructure traffic and the tenant traffic. This provides the required isolation between infrastructure and tenant traffic, and lessens the impact of tenant traffic on overall bandwidth availability. Windows Server 2012 QoS policies can be used to provide minimum and maximum bandwidth availability for each cloud infrastructure traffic profile.
- **No dedicated adapters for any traffic profile.** In this design pattern, all traffic moves through the same network adapters over the same physical network. Infrastructure traffic and tenant traffic share the same physical adapter or adapter team. Hyper-V QoS policies are applied so that each traffic profile has a guaranteed amount of bandwidth. VLAN tagging or Hyper-V virtual switch port ACLs can be used to provide the necessary isolation between cloud infrastructure and tenant traffic. This pattern requires that infrastructure traffic flow through virtual network adapters that are created on the same Hyper-V virtual switch through which tenant traffic also flows. The advantage of this converged networking pattern is that it is simpler to manage, is more cost effective and enables you to take advantage of security and performance capabilities included with the Hyper-V virtual switch.

Note that the conversation to this point has been focused on traffic patterns and network design for compute node cluster traffic. If you have chosen to separate your compute and file server clusters so that you can scale compute and storage separately, then you will need to consider what traffic profiles need to be defined on the file server cluster.

The file server cluster will have the management, cluster/CSV, and perhaps a storage network, depending on how you decide to present block storage to the file server cluster. There will be no Live Migration traffic profile on the storage cluster. But you may want to define a file server network traffic profile, which delineates the path that connects the compute node to the file server node using the SMB 3.0 protocol.

Hyper-V Guest Virtual Machine Design

Standardization is a key tenet of private cloud architectures. This also applies to virtual machines. A standardized collection of virtual machine templates can both drive predictable performance and greatly improve capacity planning capabilities. These templates also provide the foundation for your private cloud's service catalog. The service catalog can also be used to help you determine how you size the hosts in your private cloud as well as the scale units you might wish to define.

As an example, the table below illustrates what a basic virtual machine template library might look like.

Template	Specs	Network	Operating System	Unit Cost
Template 1: Small	1 vCPU, 2 GB memory, 50 GB disk, 100Mbps	VLAN 20	Windows Server 2008 R2	1
Template 2: Medium	4 vCPU, 4 GB memory, 250 GB disk, 400Mbps	VLAN 20	Windows Server 2008 R2	2
Template 3: Extra-Large	16 vCPU, 16 GB memory, 500 GB disk, 800Mbps	VLAN 20	Windows Server 2008 R2	4
Template 4: Small	1 vCPU, 2 GB memory, 50 GB disk, 100Mbps	VLAN 10	Windows Server 2012	1
Template 5: Medium	4 vCPU, 4 GB memory, 250 GB disk, 400Mbps	VLAN 10	Windows Server 2012	2
Template 6: Extra-Large	16 vCPU, 16 GB memory, 500 GB disk, 800Mbps	VLAN 10	Windows Server 2012	4

Virtual Machine Storage

This section discusses the different types of Hyper-V disks. Note that while in the past Microsoft recommended using only fixed VHDs for production, significant improvements to the virtual disk format (.VHDX) have made using dynamically expanding disks a viable format for production use. Therefore, for performance reasons, you can use either fixed or dynamically expanding disks in your private cloud infrastructure.

Dynamically Expanding Disks

Dynamically expanding virtual hard disks provide storage capacity as needed to store data. The size of the VHDX file is small when the disk is created and grows as data is added to the disk. In Windows Server 2012 the size of the VHDX file will shrink automatically when data is deleted from the virtual hard disk. Dynamically expanding disks can be provisioned very quickly and can be used as part of your thin provisioning scheme.

Fixed Size Disks

Fixed virtual hard disks provide storage capacity by using a VHDX file that is in the size specified for the virtual hard disk when the disk is created. The size of the VHDX file remains 'fixed' regardless of the amount of data stored, similar to a physical hard disk. However, you can use the Edit Virtual Hard Disk Wizard to increase the size of the virtual hard disk, which increases the size of the VHDX file. By allocating the full capacity at the time of creation, fragmentation at the host level is not an issue (fragmentation inside the VHD itself must be managed within the guest). A disadvantage of fixed sized disks is that they can take a long time to be provisioned, the time depending on the size of the fixed size disk. Fixed disks can provide incremental performance improvement. You should weigh the advantages and disadvantages of using dynamically expanding disks versus fixed sized disks by considering whether the disk space advantages conferred by the dynamically expanding disks outweigh the incremental performance improvement in fixed sized disks.

Differencing Disks

Differencing virtual hard disks provide storage to enable you to make changes to a parent virtual hard disk without altering that disk. The size of the VHD file for a differencing disk grows as changes are stored to the disk. Differencing disks are useful in lab/test environments but can also be used in private cloud infrastructure deployments.

For example, you might want to configure your compute node host infrastructure to use a combination iSCSI and VHDX boot. Given that there is minimal state required on Hyper-V compute cluster nodes, each host can have its own differencing disk. When updates to the operating system are required, the parent disk is serviced and the compute nodes are rebooted after virtual machines are migrated away from the compute node host. A new differencing disk is created at that point. This enables centralized management of a single golden image that can be used for each compute cluster host and significant reduces the amount of storage required to host the cluster node virtual disk files.

Pass-Through Disks

Hyper-V enables virtual machine guests to directly access local disks or SAN LUNs that are attached to the physical server without requiring the volume to be presented to the host server. The virtual machine guest accesses the disk directly (utilizing the disk's GUID) without having to utilize the host's file system. Given that the performance difference between fixed-disk and pass-through disks is negligible in Windows Server 2012, the decision is now based on manageability.

For instance, if the data on the volume will be very large (hundreds of gigabytes or terabytes), a VHDX is hardly portable at that size given the extreme amounts of time it takes to copy. Also, bear in mind the backup scheme. With pass-through disks, the data can only be backed up from within the guest. In addition, virtual machine portability will be limited.

Also note that when utilizing pass-through disks, there is no VHDX file created; the LUN is used directly by the guest. Since there is no VHDX file, there is no dynamic sizing capability or snapshot capability.

Support for Guest Clustering

Creating a guest cluster gives you the ability to failover or migrate your applications independently of the guest operating system and provides you the ability to decouple the application from the guest operating system in a way similar the abstraction that the guest operating system gets from virtualization. In the case of the guest operating system itself, you are decoupling the guest operating system from the hardware. With a guest cluster you decouple the application from the virtual machine. This gives you much greater flexibility and increased uptime in the event that the virtual machine has a failure in which a migration or restart of the VM will not solve.

Windows Server 2012 provides support for guest clustering and access to shared storage required for guest clustering with:

- In-Guest iSCSI Initiator
- In-Guest Fibre Channel synthetic HBA (new in Windows Server 2012)

In-Guest iSCSI Initiator

Hyper-V can also utilize iSCSI storage by directly connecting to iSCSI LUNs utilizing the guest's virtual network adapters. This is mainly used for access to large volumes, volumes on SANs that the Hyper-V host itself is not connected to, or for guest-clustering. Guests cannot boot from iSCSI LUNs accessed through the virtual network adapters without utilizing a third-party iSCSI initiator. However, given that guests can boot from SMB 3.0 file shares, there is no advantage to using iSCSI boot for virtual machines.

In-Guest Fibre Channel Synthetic HBA

A new feature in Windows Server 2012 allows you to connect directly to Fibre Channel storage from within the guest operating system that runs in a virtual machine. This feature makes it possible to virtualize workloads and applications that require direct access to Fibre Channel-based storage. It also makes it possible to configure clustering directly within the guest operating system. This feature makes HBA ports available within the guest operating system.

Hyper-V can utilize Fibre Channel storage by directly connecting to Fibre Channel LUNs utilizing the guest's virtual HBAs. This is mainly used for access to large volumes, volumes on SANs which the Hyper-V host itself is not connected to, or for guest-clustering. Guests cannot boot from Fibre Channel LUNs accessed through the virtual network adapters without utilizing a third-party

Fibre Channel HBA. However, similar to the situation with iSCSI boot, given that guests can boot from SMB 3.0 file shares, there is no advantage to using Fibre Channel boot for virtual machines.

For more information about the in-guest Fibre Channel HBA, see Hyper-V Virtual Fibre Channel Overview.

Virtual Machine Network Interfaces

Hyper-V guests support two types of virtual network adapters: synthetic and emulated. Synthetic makes use of the Hyper-V VMBUS architecture and is the high-performance, native device. Synthetic devices require the Hyper-V integration services be installed within the guest. Emulated adapters are available to all guests even if the integration services are not available. They are much slower performing, and should only be used if synthetic is unavailable.

Note
When you configure a virtual machine to perform a PXE boot for installation, it will initially configure itself to use an emulated adapter. If you wish to take advantage of the synthetic adapter, you will need to change the adapter type after installation completes.

You can create many virtual networks on the server running Hyper-V to provide a variety of communications channels. For example, you can create networks to provide the following:

- Communications between virtual machines only. This type of virtual network is called a private network.
- Communications between the host server and virtual machines. This type of virtual network is called an internal network.
- Communications between a virtual machine and a physical network by creating an association to a physical network adapter on the host server. This type of virtual network is called an external network.

Virtual Processors

In Windows Server® 2008 R2, Hyper-V supported a maximum ratio of 8 virtual processors per 1 logical processor for server workloads, and 12 virtual processors per 1 logical processor for VDI workloads. A logical processor is defined as a processing core seen by the host operating system or parent partition. In the case of Intel Hyper-Threading Technology, each thread is considered a logical processor.

Therefore a 16 logical-processor server supports a maximum of 128 virtual processors. That would in turn equate to 128 single-processor virtual machines, 64 dual-processor virtual machines, or 32 quad-processor virtual machines. The 8:1 or 12:1 virtual to logical processor ratios are maximum supported limits; it is recommended that lower limits be utilized than the maximum.

In Windows Server 2012, there are no hard or soft coded virtual to logical processor ratios. The recommendation is use dual socket servers with the highest core density available. When planning on scale units and how many virtual machines the scale unit will support, it's more effective to consider the amount of RAM you will require, as discussed earlier. If more nodes are

required to provide required processing power, you can add more nodes to your scale unit. Historical trend analysis will be useful in this context. Trends and thresholds are more important than specific ratios.

Overview of Suggested Cloud Infrastructure Deployment Scenarios

Throughout this document you have been presented with hundreds of potential options for how to design a private cloud infrastructure from the storage, networking and compute perspectives. The possible permutations are virtually limitless and you might find it a bit challenging to determine which options would work best for you, and which options work best together. You may even be interested in whether there are tested private cloud infrastructure design patterns that you can use to get your infrastructure started.

To help you in your testing and evaluation of a Microsoft private cloud infrastructure, we have worked on developing and testing three private cloud infrastructure design patterns that you may want to adopt in your own private cloud environment. These design patterns:

- Represent a hardware and software configuration that has been demonstrated to work in the Microsoft Enterprise Engineering Center (EEC)
- Provide three options that you may want to choose from, where many of the design decisions have been made for you
- Help you to better understand how you can take advantage of the many improvements in Windows Server 2012 to get the most out of your private cloud infrastructure investments.

The three design patterns that we've identified and documented are:

- The Non-Converged Data Center Configuration
- The Converged Data Center with File Server Storage Configuration
- The Converged Data Center without Dedicated Storage Configuration

It is important to note that within the context of these three configurations, the term "converged" refers to the networking configuration. A converged networking design consolidates multiple traffic profiles onto a single network adapter (or team) and network and then uses a variety of software constructs to provide the required isolation and Quality of Service for each profile.

Finally, be aware that while these three cloud infrastructure design patterns have made a number of decisions regarding storage, networking and compute functions for you, they do not span the entire gamut of options made available to you through Windows Server 2012. You may want to begin with these patterns and build on top of them by taking advantage of other Windows Server 2012 platform capabilities.

The Non-Converged Data Center Configuration

The Non-Converged Data Center Configuration cloud infrastructure design pattern is aimed at allowing for easy upgrade of an existing cloud infrastructure based on networking design decisions and hardware configuration recommendations for a Windows Server 2008 R2

infrastructure. The Non-Converged Data Center Configuration focuses on the following key requirements in the areas of networking, compute and storage:

Networking

- You have an existing investment in separate networks based on the recommended configuration of Hyper-V in Windows Server 2008 R2 and you require that physical network traffic segmentation be kept in place to avoid re-architecting your network. Each type of infrastructure traffic (management, cluster/CSV, Live Migration and storage) and tenant traffic are carried over physically separate networks and network adapters. This requirement is met by installing physically separate NICs for each traffic type and assigning VLAN 802.1q tags to each adapter. Alternatively, you can avoid using VLAN tagging and use port based VLANs on your network switches.
- You require that each traffic type is dedicated to a specific adapter. This requirement is met by configuring each of the traffic flows to use the correct subnet/IP address on the dedicated NIC.
- You require that virtual machine workloads have access to the highest network performance possible. This requirement is met by using the new Windows Server 2012 Single Root I/O Virtualization (SR-IOV) feature, which enables the virtual machines running on the Hyper-V server to have direct access to the network adapter hardware, thus bypassing the virtual networking stack.

Storage

- You have an existing investment in Fibre Channel or iSCSI SANs and require well-connected storage so that all members of the Hyper-V failover cluster are connected to block storage. This requirement is met by configuring your Hyper-V hosts to keep using the traditional SAN storage. Each member of the Hyper-V failover cluster can connect to iSCSI, Fibre Channel or Fibre Channel over Ethernet.
- You require that each member of the Hyper-V failover cluster be able to access the shared storage. This requirement is met by using Windows Server 2012 Failover Clustering and Cluster Shared Volumes Version 2 (CSV v2) volumes to store virtual machine files and metadata.

Compute

1. You require that you are able to repurpose previous Hyper-V hardware that ran Windows Server 2008 R2 servers. This requirement is met by reusing previous hardware and making a single change to the hardware configuration, which is to add a 10 GB network adapter that supports SR-IOV. In addition, you will need to update the BIOS if it doesn't current support SR-IOV. Alternatively, you could use a 1 GbE adapter and not deploy SR-IOV. In this document we will demonstrate how to use SR-IOV.
2. You require that access to virtual machines is resilient to hardware failure. This requirement can be met by using Windows Server 2012 Failover Clustering together with the Hyper-V Server Role.

Overview of the Non-Converged Data Center Configuration

The Non-Converged Data Center cloud configuration consists of the following:

- Multiple computers in a Hyper-V failover cluster serving both the compute and storage roles.A Hyper-V cluster is created using the Windows Server 2012 Failover Cluster feature. The Windows Server 2012 Failover Clustering feature set is tightly integrated with the Hyper-V server role and enables a high level of availability from a compute and networking perspective. In addition, Windows Server 2012 Failover Clustering enhances virtual machine mobility and management which is critical in a cloud environment.
- A non-converged networking infrastructure that supports multiple cloud traffic profiles.Each computer in the Hyper-V failover cluster must have enough network adapters installed to support each traffic type that needs to be isolated from other traffic types. In most cases, this will include network adapters that are assigned to infrastructure traffic such as management, cluster/CSV, and Live Migration. If you decide to use an Ethernet-based storage protocol (such as iSCSI or FCoE), then you will also need a network adapter for the storage traffic. The infrastructure traffic network adapters in this scenario are non-teamed 1 GB adapters, although you can use 10 GB adapters or mix 1 GB and 10 GB adapters for the infrastructure traffic types you need to support. In addition, you also have the option of teaming any adapters you like, with the caveat being that RDMA is not supported on teamed adapters. The tenant traffic adapter is a 10 GB adapter that supports SR-IOV and is not teamed because SR-IOV and NIC Teaming are not compatible.
- SAN-based storage that can be Ethernet or non-Ethernet based. Storage options include iSCSI, Fibre Channel, Fibre Channel over Ethernet or Infiniband (non-Ethernet). You can also choose to use SAS storage together with Windows Server 2012 Storage Spaces.
- The appropriate networking hardware to connect all of the computers in the Hyper-V cluster to each other and to a larger network from which the hosted virtual machines are available.

The specific design pattern documented in the Non-Converged Data Center Configuration scenario includes the following:

- Multiple computers in a Hyper-V failover cluster
- Separate 1 GB network adapters over which live migration, cluster, management, and tenant traffic traverse.
- One 10 GB adapter that is dedicated to tenant traffic that supports SR-IOV. Note that in the SR-IOV scenario that all traffic bypasses the Hyper-V virtual switch, so all traffic isolation depends on the capabilities the unique SR-IOV NIC may provide in this area.
- SAN storage based on iSCSI, Fibre Channel, Fibre Channel over Ethernet or Infiniband.

Figure 3 depicts the Non-Converged Enterprise configuration.

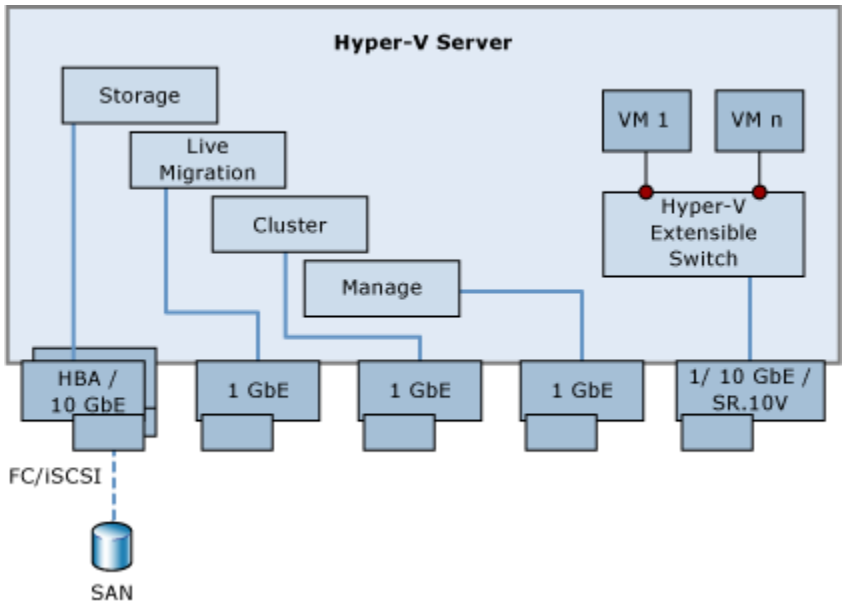

Figure 3: High level overview of cluster member networking configuration

This configuration highlights the following technologies and features of Windows Server 2012:

- Failover Clustering: A failover cluster is a group of independent computers that work together to increase the availability and scalability of clustered roles (formerly called clustered applications and services). The clustered servers (called nodes) are connected by physical cables and by software. If one or more of the cluster nodes fail, other nodes begin to provide service (a process known as failover). In addition, the clustered roles are proactively monitored to verify that they are working properly. If they are not working, they are restarted or moved to another node. With the Failover Clustering feature, users experience a minimum of disruptions in service.
- Single Root I/O Virtualization: Single Root I/O Virtualization (SR-IOV) is a standard introduced by the PCI-SIG. SR-IOV works in conjunction with system chipset support for virtualization technologies. This provides remapping of interrupts and DMA and allows SR-IOV capable devices to be assigned directly to a virtual machine. Hyper-V in Windows Server 2012 enables support for SR-IOV–capable network devices and allows an SR-IOV virtual function of a physical network adapter to be assigned directly to a virtual machine. This increases network throughput and reduces network latency, while also reducing the host CPU overhead required for processing network traffic.

Note

At least one Active Directory Domain Services (AD DS) domain controller is needed for centralized security and management of the cluster member computers (not shown). It must be reachable by all of the cluster member computers, including the members of the shared storage cluster. DNS services are also required and are not depicted.

For detailed setup and configuration information that you can use to build the Non-Converged Data Center Configuration in your own datacenter, please see Building Your Cloud Infrastructure: Non-Converged Data Center Configuration.

The Converged Data Center with File Server Storage Configuration

The Converged Datacenter with File Server Storage cloud design pattern is essentially defined by the fact that the Hyper-V computer cluster is separate from the storage cluster. In the Non-Converged Datacenter Configuration cloud design pattern, the Hyper-V cluster was attached to block storage. In contrast, the Converged Data Center with File Server Storage Configuration uses a highly available file server cluster to host the VHDX and virtual machine configuration files. The nodes on the Hyper-V compute cluster access the virtual machine files over the network using the SMB 3.0 protocol. In addition, the Converged Data Center with File Server Storage Configuration uses a converged network pattern on the Hyper-V compute cluster where the infrastructure traffic profiles (management, cluster/CSV, Live Migration and storage) are hosted on one subnet/NIC and the tenant traffic is hosted on a separate subnet/NIC.

The Converged Data Center with File Server Storage Configuration uses:

- Two subnets - one for cloud infrastructure traffic (live migration, cluster, storage and management) one for tenant traffic.
- NIC Teaming for network bandwidth aggregation and failover for the infrastructure and tenant subnet.
- A dedicated file server storage cluster that hosts virtual machine VHDX and configuration files.
- A dedicated Hyper-V compute cluster that runs the virtual machine workloads.

Design Considerations and Requirements for the Converged Data Center with File Server Storage Pattern

The Converged Data Center with File Server Storage cloud infrastructure design pattern focuses on the following key requirements in the areas of networking, compute and storage:

Networking

- You require that cloud infrastructure traffic be physically separated from cloud tenant traffic. The requirement is met by creating separate NICs (or teams) for infrastructure and tenant traffic and connecting them to different subnets/segments. The tenant subnet may use NIC Teaming if you like in this scenario.
- You require that infrastructure traffic (i.e. live migration, cluster, storage, management) all receive guaranteed levels of bandwidth. The requirement is met by using Windows QoS policies on the parent Hyper-V partition.
- You require that tenant traffic from different tenants receive guaranteed levels of bandwidth. The requirement is met by using Hyper-V virtual switch QoS policies.

Storage

- You require the ability to scale and manage storage separately from the compute infrastructure. This requirement can be met by creating a dedicated storage cluster that will host the VHDX and virtual machine configuration files. The Hyper-V compute cluster will connect to the file server cluster using SMB 3.0 to connect to file shares on the storage

cluster. The file server cluster will be configured to use the new Windows Server 2012 Scale-out File Server feature so as to provide continuous availability of the virtual machine files.

- You require a low cost storage option. This requirement is met by using Serial Attached SCSI (SAS) disks in shared JBOD enclosures managed through Storage Spaces. Alternatively, if you have existing investments in other storage technologies, each member of the file server failover cluster can connect to iSCSI, Fibre Channel or Fibre Channel over Ethernet.
- You require a resilient storage solution. This requirement is met by using at least two file servers configured as a failover cluster, with well-connected (shared JBODs) storage so that all members of the file server failover cluster are directly connected to storage with Storage Spaces configured as a mirrored space to guarantee against data loss in the case of disk failures. Each cluster member has redundant connections to the JBOD enclosure and Windows Server 2012 MPIO is enabled. In addition, each member of the file server failover cluster is able to access the shared storage by using Windows Server 2012 Failover Clustering and Cluster Shared Volumes Version 2 (CSV v2) volumes to store virtual machine files and metadata.

Compute

1. You require the ability to scale your compute infrastructure separately from your storage infrastructure. This requirement is met by creating a dedicated Hyper-V compute cluster that connects to remote file server storage for virtual machines and virtual machine configuration files. Local disks on the compute nodes are only used for the boot partition but not for the virtual machines.
2. You require that virtual machines will be continuously available and resilient to hardware failures. This requirement can be met by using Windows Server 2012 Failover Clustering together with the Hyper-V Server Role.
3. You require the highest number of virtual machines possible per host server (i.e. increased VM density). This requirement is met by using processor offload technologies, such as Remote Direct Memory Access (RDMA), Receive Side Scaling (RSS), Receive Side Coalescing (RSC), and Datacenter Bridging (DCB).

Overview of the Converged Data Center with File Server Storage Configuration

Based on the above requirements, the Converged Data Center with File Server Storage Configuration has the following characteristics:

- Multiple computers in a dedicated Hyper-V compute cluster.A Hyper-V cluster is created using the Windows Server 2012 Failover Cluster feature. The Windows Server 2012 Failover Clustering feature set is tightly integrated with the Hyper-V server role and enables a high level of availability from a compute and networking perspective. In addition, Windows Server 2012 Failover Clustering enhances virtual machine mobility and manageability which is critical in a cloud environment. The Hyper-V cluster is a dedicated compute cluster and does not host storage for virtual machines and virtual machine configuration files.
- Multiple computers in a dedicated Scale-out File Server storage cluster.A File Server failover cluster is created using the Windows Server 2012 Failover Cluster feature. Windows Server 2012 includes a new file server capability known as "Scale-out File Server for applications" that enables you to store virtual machine and virtual machine configuration files in a file share

and make these files continuously available. When you separate the file server cluster from the compute cluster you are able to scale compute and storage resources independently.

- A converged networking infrastructure that supports physical segmentation of infrastructure and tenant traffic.Each computer in the Hyper-V failover cluster must have at least two network adapters so that one adapter can host the cloud infrastructure traffic and one adapter can support tenant traffic. If resiliency against NIC failures is required, then you can add additional network adapters on each of the networks, and team them using Windows Server 2012 Load Balancing and Failover (LBFO) NIC Teaming. The NICs can be 10 GbE or 1 GbE network adapters. These NICs will be used for live migration, cluster, storage, management (together referred to as "infrastructure" traffic) and tenant traffic. However, keep in mind that NIC Teaming is not compatible with RDMA and is the reason why RDMA is not enabled on the infrastructure network.
- The appropriate networking hardware (e.g. Ethernet switches, cables, etc.) to connect all of the computers in the Hyper-V cluster to each other and to a larger network from which the hosted virtual machines are available.

Figure 4 provides a high-level view of the scenario layout. Key elements of the configuration include:

- A File Server cluster that hosts the virtual hard disks and virtual machine configuration files
- The File Server cluster is connected only to the infrastructure network
- The File Server cluster is connected to block storage either through HBAs or over a 10 GB Ethernet network (as in the case of iSCSI or Fibre Channel of Ethernet [FCoE])
- A Hyper-V compute cluster that hosts the virtual machine workloads.
- The Hyper-V compute cluster is connected to the datacenter (infrastructure) network and the tenant network using teamed network adapters.
- Cloud infrastructure traffic flows to and from the host-based 10GbE network adapter team
- Tenant network traffic to and from the virtual machines flows through the Hyper-V virtual switch which is bound to the Tenant Network NIC team.

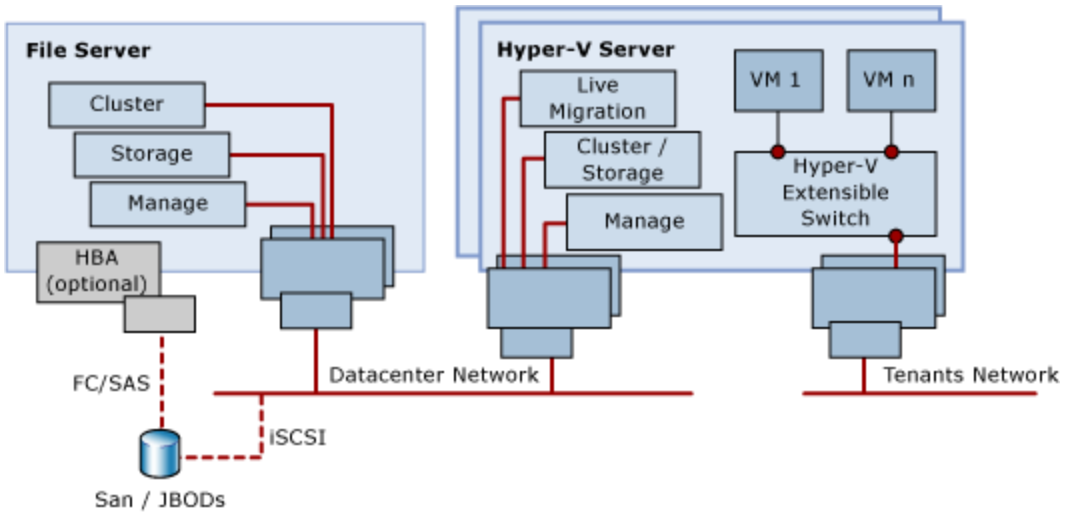

Figure 4: High level overview of Converged Datacenter with File Server storage infrastructure design pattern

Note

Although this configuration uses SAS storage on the file server cluster, you can easily choose to use other types of storage, such as iSCSI or Fibre Channel-based SAN storage. You can find more information about storage configuration for a non-SAS scenario in the document Building Your Cloud Infrastructure: Non-Converged Data Center Configuration, which describes how to configure the SAN storage.

Note

At least one Active Directory Domain Services (AD DS) domain controller is needed for centralized security and management of the cluster member computers (not shown). It must be reachable by all of the cluster member computers, including the members of the shared storage cluster. DNS services are also required and are not depicted.

This configuration highlights the following technologies and features of Windows Server 2012:

- **Load Balancing and Failover (LBFO)**: Load Balancing and Failover (NIC Teaming) logically combines multiple network adapters to provide bandwidth aggregation and traffic failover to prevent connectivity loss in the event of a network component failure. Load Balancing with Failover is also known as NIC Teaming in Windows Server 2012.
- **Windows Server Quality of Service (QoS)**: Windows Server 2012 includes improved QoS features that lets you manage bandwidth and provide predictable network performance to traffic to and from the host operating system.
- **Hyper-V Extensible Switch Quality of Service (QoS)**: In Windows Server 2012, The Hyper-V extensible switch includes QoS features that can be applied on virtual switch ports, and that lets you manage bandwidth and provide predictable network performance to virtual machines running on that server.
- **Data Center Bridging (DCB)**: DCB provides hardware-based bandwidth allocation to a specific type of traffic and enhances Ethernet transport reliability with the use of priority-based flow control. Hardware-based bandwidth allocation is essential if traffic bypasses the operating system and is offloaded to a converged network adapter, which might support Internet Small Computer System Interface (iSCSI), Remote Direct Memory Access (RDMA) over Converged Ethernet, or Fiber Channel over Ethernet (FCoE).
- **Storage Spaces**: Storage Spaces makes it possible for you to create cost-effective disk pools that present themselves as a single mass storage location on which virtual disks or volumes can created and formatted.

For detailed setup and configuration information that you can use to build the Non-Converged Data Center Configuration in your own datacenter, please see Building Your Cloud Infrastructure: Converged Data Center with File Server Storage.

The Converged Data Center without Dedicated Storage Nodes Configuration

The Converged Data Center without Dedicated Storage Nodes cloud infrastructure design pattern takes advantage of new capabilities in Windows Server 2012 that enable you to converge all traffic profiles (infrastructure and tenant) to run through a single network adapter or NIC Team. This differs from the previous two design patterns, where in the first one each traffic profile was dedicated to a physical network adapter and where in the second design pattern infrastructure traffic and tenant traffic were carried over different network adapters and subnets. The Converged Data Center without Dedicated Storage Nodes cloud design pattern can greatly simplify your cloud infrastructure by reducing the number of cables and ports you need to deal with.

The Converged Datacenter without Dedicated Storage Nodes Configuration includes:

- A converged network infrastructure for live migration, cluster, storage, management, and tenant traffic
- All network traffic moves through the Hyper-V virtual switch, this includes the host operating system traffic that moves over the infrastructure network.
- Hyper-V Virtual Switch Quality of Service (QoS)
- Hyper-V Virtual Switch port ACLs and 802.1q VLAN tagging
- NIC Teaming for network bandwidth aggregation and failover
- Well-connected storage using SAS JBOD enclosures

Design Considerations and Requirements for the Converged Data Center without Dedicated Storage Node Pattern

The Converged Data Center without Dedicated Storage Nodes cloud infrastructure design pattern focuses on the following key requirements in the areas of networking, compute and storage:

Networking

- You prefer that network traffic to and from both the host operating system and the guest operating systems running on the host move through a single network adapter team. This requirement is met by using Windows Server 2012 NIC Teaming (LBFO) and passing all traffic through the Hyper-V virtual switch.
- You require that live migration, cluster, storage, management and tenant traffic all receive guaranteed levels of bandwidth. The requirement is met by using Hyper-V virtual switch QoS policies.
- You require that infrastructure traffic (which includes Live Migration, cluster, storage and management traffic) and tenant traffic be isolated from each other. This requirement is met by using Hyper-V virtual switch port ACLs and 802.1q VLAN tagging.

Storage

- You prefer to scale your cloud infrastructure by adding scale units consisting of compute and storage capacity together. This requirement is met by connecting the Hyper-V servers directly to SAS storage, without having dedicated file servers. Note that you can also use SAN based storage connected to the compute cluster in this design pattern.

- You require cost-effective storage. This requirement is met by using SAS disks in shared JBOD enclosures managed through Storage Spaces.
- You require a resilient storage solution. This requirement is met by having multiple Hyper-V servers configured as a failover cluster, and having a well-connected (shared JBODs) storage so that all members of the failover cluster are directly connected to storage, and by having Storage Spaces configured as a mirrored space to guarantee against data loss in the case of disk failures
- You require that each member of the Hyper-V failover cluster be able to access the shared storage where the VHDs are located. This requirement is met by using Windows Server 2012 Failover Clustering and Cluster Shared Volumes Version 2 (CSV v2) volumes to store virtual machine files and metadata.

Compute

- You require that the virtual machines will be continuously available and resilient to hardware failures. This requirement can be met by using Windows Server 2012 Failover Clustering together with the Hyper-V Server Role.
- You require the highest number of virtual machines possible per host server (i.e. increased density). This requirement is met by using processor offload technologies, such as Remote Direct Memory Access (RDMA), Receive Side Scaling, Receive Side Coalescing (RSC), and Datacenter Bridging (DCB). Please note that in the default configuration presented here (without a dedicated storage access NIC), RDMA and DCB cannot be used because these technologies require direct access to the hardware and must bypass much of the virtual networking stack and this compatible with NIC Teaming. This is similar to the situation with Single Root I/O Virtualization (SR-IOV). For optimal performance, especially in the context of network access to storage, a separate NIC team would be required to support these hardware offload acceleration technologies.

The Converged Datacenter without Dedicated Storage nodes cloud infrastructure design pattern consists of the following:

- Multiple computers in a Hyper-V failover cluster. A Hyper-V cluster is created using the Windows Server 2012 Failover Cluster feature. The Windows Server 2012 Failover Clustering feature set is tightly integrated with the Hyper-V server role and enables a high level of availability from a compute and networking perspective. In addition, Windows Server 2012 Failover Clustering enhances virtual machine mobility which is critical in a cloud environment. For example, Live Migration is enhanced when performed in a failover cluster deployment because the cluster can automatically evaluate which node in the cluster is optimal for migrated virtual machine placement.
- A converged networking infrastructure that supports multiple cloud traffic profiles. Each computer in the Hyper-V failover cluster should have at least two network adapters that will be used for the converged network. This converged network will host all traffic to and from the server, which includes both host system traffic and guest/tenant traffic. The network adapters will be teamed by using Windows Server 2012 Load Balancing and Failover (LBFO) NIC Teaming. The NICs can be either two or more 10 GbE or 1 GbE network adapters. These NICs will be used for live migration, cluster, storage, management (together referred to as "infrastructure" traffic) and tenant traffic.

- The appropriate networking hardware to connect all of the computers in the Hyper-V cluster to each other and to a larger network from which the hosted virtual machines are available.

The following figure provides a high-level view of the scenario architecture. The teamed network adapters on each member of the failover cluster are connected to what will be referred to as a converged subnet in this document. We use the term converged subnet to make it clear that all traffic to and from the Hyper-V cluster members and the tenant virtual machines on each cluster member must flow through the teamed converged subnet network adapter. Both the host operating system and the tenants connect to the network through the Hyper-V virtual switch. The figure also shows an optional network adapter that is RDMA-capable that can be used for storage traffic, such as when storage is being hosted on a share on a remote file server.

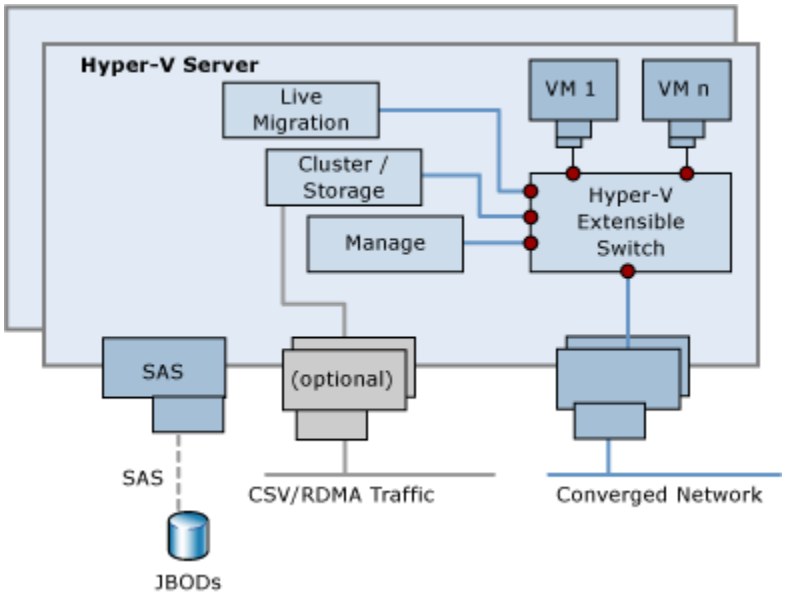

Figure 5 High level overview of cluster member networking configuration

Note

At least one Active Directory Domain Services (AD DS) domain controller is needed for centralized security and management of the cluster member computers (not shown). It must be reachable by all of the cluster member computers, including the members of the shared storage cluster. DNS services are also required and are not depicted.

Figure 6 provides an overview of traffic flows on each member of the Hyper-V cluster. The figure calls out the following significant issues in the configuration:

- Each cluster node member uses a virtual network adapter to connect to the Hyper-V Extensible Switch, which connects it to the physical network.
- Each tenant virtual machine is also connected to the Hyper-V Extensible Switch using a virtual network adapter.
- Network adapters named ConvergedNet1 and ConvergedNet2 participate in a teamed physical network adapter configuration using the Windows Server 2012 Failover and Load Balancing feature.

- Windows Server 2012 Hyper-V virtual switch QoS is used to assure that each traffic type (such as live migration, cluster, management and tenant) has a predictable amount of bandwidth available.
- Traffic isolation is enabled by 802.1q VLAN tagging so that host traffic is not visible to the tenants.
- Windows Server 2012 Hyper-V virtual switch port ACLs can also be used for more granular access control at the network level.

It is important to note that Remote Direct Memory Access (RDMA) cannot be used on the converged network because it does not work together with the Hyper-V virtual switch and NIC Teaming. This will be an issue if you prefer to use high performance SMB 3 connectivity to file server based storage for virtual machine disk and configuration files.

Note

Virtual local area networks (VLANs) are not assigned to each tenant because VLAN-based network isolation is not a scalable solution and is not compatible with Windows Server 2012 network virtualization. VLANs are used to isolate infrastructure traffic from tenant traffic in this scenario.

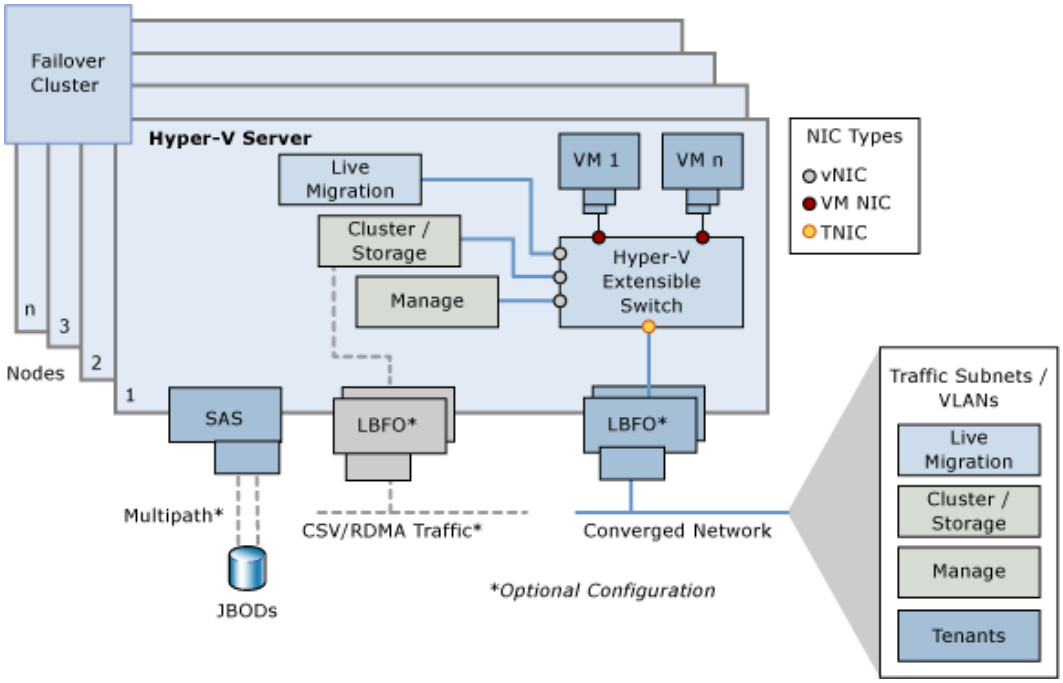

Figure 6 Overview of cluster member traffic flows

This configuration highlights the following technologies and features of Windows Server 2012:

- **Load Balancing and Failover (LBFO)**: Load Balancing and Failover logically combines multiple network adapters to provide bandwidth aggregation and traffic failover to prevent connectivity loss in the event of a network component failure. Load Balancing with Failover is also known as NIC Teaming in Windows Server 2012.

- **Hyper-V Virtual Switch Quality of Service (QoS)**: In Windows Server 2012, QoS includes new bandwidth management features that let you provide predictable network performance to virtual machines on a server running Hyper-V.
- **Hyper-V Virtual Switch Quality of Service (QoS)**: In Windows Server 2012 the Hyper-V virtual switch includes new capabilities that enhance the security of the cloud infrastructure. You can now use Port Access Control Lists (Port ACLs) and VLAN support to get network isolation similar to what you find when using physical network isolation.
- **Storage Spaces**: Storage Spaces makes it possible for you to create cost-effective disk pools that present themselves as a single mass storage location on which virtual disks or volumes can created and formatted.

For detailed setup and configuration information that you can use to build the Non-Converged Data Center Configuration in your own datacenter, please see Building Your Cloud Infrastructure: Converged Data Center without Dedicated Storage Nodes.

Building Your Cloud Infrastructure: Non-Converged Data Center Configuration

This document contains the instructions that you need to follow to create a private or public cloud configuration that uses:

- Separate network adapters for live migration, cluster, management, and tenant traffic
- Traditional SAN storage
- Optionally use Single Root I/O Virtualization (SR-IOV)

The design pattern discussed in this document is one of three design patterns we suggest for building the core cloud compute and storage infrastructure. For information about the other two cloud infrastructure design patterns, please see:

- Building Your Cloud Infrastructure: Converged Data Center without Dedicated Storage Nodes
- Building Your Cloud Infrastructure: Converged Data Center with File Server Storage

Design Considerations and Requirements for the Non-Converged Data Center Configuration Pattern

The Non-Converged Data Center Configuration cloud infrastructure design pattern focuses on the following key requirements in the areas of networking, compute and storage:

Networking

- You have an existing investment in separate networks based on the recommended configuration of Hyper-V in Windows Server® 2008 R2 and you require that this physical network traffic segmentation be kept in place to avoid re-architecting your network. Each type of infrastructure traffic (management, cluster/CSV, Live Migration and storage) and tenant traffic are carried over physically separate networks and network adapters. This requirement

is met by installing physically separate NICs for each traffic type and assigning VLAN 802.1q tags to each adapter.

- You require that each traffic type is dedicated to a specific adapter. This requirement is met by configuring each of the traffic flows to use the correct subnet/IP on the dedicated NIC.
- You require that the virtual machine workload has access to the highest network performance possible. This requirement is met by using the new Windows Server® 2012 Single Root I/O Virtualization (SR-IOV) feature, which enables the virtual machines running on the Hyper-V server to have direct access to the network adapter hardware, thus bypassing the virtual networking stack.

Storage

- You have an existing investment in FC or iSCSI SANs and require well-connected storage so that all members of the Hyper-V failover cluster are connected to block storage. This requirement is met by configuring your Hyper-V hosts to keep using the traditional SAN storage. Each member of the Hyper-V failover cluster can connect to iSCSI, Fibre Channel or Fibre Channel over Ethernet.
- You require that each member of the Hyper-V failover cluster be able to access the shared storage. This requirement is met by using Windows Server 2012 Failover Clustering and Cluster Shared Volumes Version 2 (CSV v2) volumes to store virtual machine files and metadata.

Compute

- You require that you are able to reuse previous Hyper-V hardware that ran Windows Server 2008 R2 server. This requirement is met by reusing previous hardware and making a single change to the hardware configuration, which is to add a 10GbE network adapter that supports SR-IOV. Alternatively, you could use a 1 GbE adapter and not deploy SR-IOV. In this document we will demonstrate how to use SR-IOV.
- You require that access to virtual machines is resilient to hardware failure. This requirement can be met by using Windows Server 2012 Failover Clustering together with the Hyper-V Server Role.

Overview

A Windows Server 2012 cloud infrastructure is a high-performing and highly available Hyper-V cluster that hosts virtual machines that can be managed to create private or public clouds using the Non-Converged Data Center Configuration infrastructure design pattern. This document explains how to configure the basic building blocks for such a cloud. It does not cover the System Center or other management software aspects of deployments; the focus is on configuring the core Windows Server hosts that are used to build cloud infrastructure.

This cloud configuration consists of the following:

- Multiple computers in a Hyper-V failover cluster.

A Hyper-V cluster is created using the Windows Server 2012 Failover Cluster feature. The Windows Server 2012 Failover Clustering feature set is tightly integrated with the Hyper-V server role and enables a high level of availability from a compute and networking perspective. In addition, Windows Server 2012 Failover Clustering enhances virtual machine mobility which is critical in a cloud environment.

- A non-converged networking infrastructure that supports multiple cloud traffic profiles.

  Each computer in the Hyper-V failover cluster must have enough network adapters installed to support each traffic type that needs to be isolated from other traffic types. In most cases, this will include network adapters that are assigned to infrastructure traffic such as management, cluster/CSV, and Live Migration. If you decide to use an Ethernet-based storage protocol (such as iSCSI or FCoE), then you will also need a network adapter for the storage traffic. The infrastructure traffic network adapters in this scenario are non-teamed 1 GB adapters, although you can use 10 GB adapters or mix 1 GB and 10 GB adapters for the infrastructure traffic types you need to support. The tenant traffic adapter is a 10 GB adapter that supports SR-IOV.
- SAN-based storage what can be Ethernet or non-Ethernet based. Storage options include iSCSI, Fibre Channel, Fibre Channel over Ethernet or Infiniband.
- The appropriate networking hardware to connect all of the computers in the Hyper-V cluster to each other and to a larger network from which the hosted virtual machines are available.

This configuration highlights the following technologies and features of Windows Server 2012:

- **Failover Clustering**: A failover cluster is a group of independent computers that work together to increase the availability and scalability of clustered roles (formerly called clustered applications and services). The clustered servers (called nodes) are connected by physical cables and by software. If one or more of the cluster nodes fail, other nodes begin to provide service (a process known as failover). In addition, the clustered roles are proactively monitored to verify that they are working properly. If they are not working, they are restarted or moved to another node. With the Failover Clustering feature, users experience a minimum of disruptions in service.
- **Single Root I/O Virtualization**: Single Root I/O Virtualization (SR-IOV) is a standard introduced by the PCI-SIG. SR-IOV works in conjunction with system chipset support for virtualization technologies. This provides remapping of interrupts and DMA and allows SR-IOV capable devices to be assigned directly to a virtual machine. Hyper-V in Windows Server 2012 enables support for SR-IOV–capable network devices and allows an SR-IOV virtual function of a physical network adapter to be assigned directly to a virtual machine. This increases network throughput and reduces network latency, while also reducing the host CPU overhead required for processing network traffic.

Non-Converged Data Center Configuration Scenario Overview

The Non-Converged Data Center Configuration scenario includes the following:

- Multiple computers in a Hyper-V failover cluster
- Separate 1 GB network adapters over which live migration, cluster, management, and tenant traffic traverse.
- One 10 GB adapter that is dedicated to tenant traffic that supports SR-IOV. Note that in this scenario that all traffic bypasses the Hyper-V virtual switch, so all traffic isolation depends on the capabilities of the unique SR-IOV may provide in this area.
- SAN storage based on iSCSI, Fibre Channel, Fibre Channel over Ethernet or Infiniband.

Figure 1 shows the Non-Converged Data Center configuration. The following are the salient aspects of this cloud infrastructure design pattern:

- SAN connectivity is enabled either via an HBA or 10 GB Ethernet connection (depending on the type of SAN deployed)
- Live Migration, Cluster/CSV and management traffic is assigned to separate 1 GB network adapters
- Virtual machine workloads connect to the tenant network using a 10 GB SR-IOV capable adapter. The Hyper-V extensible switch is configured to support SR-IOV to enable the virtual machine to communicate directly with the adapter hardware.

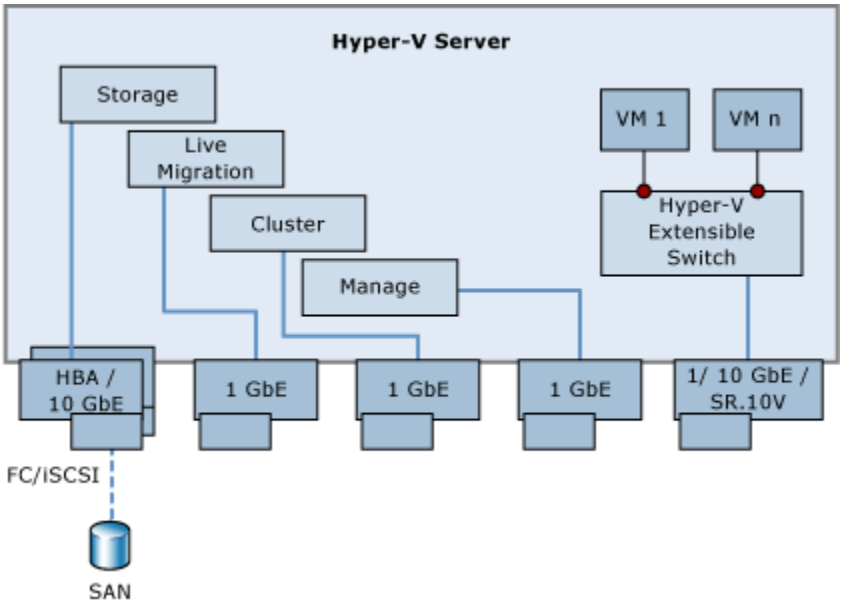

Figure 1 High level overview of cluster member networking configuration

Note

At least one Active Directory Domain Services (AD DS) domain controller is needed for centralized security and management of the cluster member computers (not shown). It must be reachable by all of the cluster member computers, including the members of the shared storage cluster. DNS services are also required and are not depicted.

The following sections describe how to set up this cloud configuration using UI-based tools and Windows PowerShell.

- After the cloud is built, you can validate the configuration by doing the following:
- Install and configure virtual machines
- Migrate running virtual machines between servers in the Hyper-V cluster (live migration)
- Failover storage from one owner to another

Install and configure

Creating this cloud infrastructure configuration consists of the following steps:

- Step 1: Initial node configuration
- Step 2: Initial network configuration
- Step 3: Initial storage configuration
- Step 4: Failover cluster setup
- Step 5: Configure Hyper-V settings
- Step 6: Cloud validation

The following table summarizes the steps that this document describes:

Step	Task	Target	Tasks

1	Initial Node Configuration	All Nodes	• 1.1-Upgrade the machine to the latest BIOS and enable BIOS settings required for Hyper-V and SR-IOV
			• 1.2-Perform a clean operating system installation
			• 1.3-Perform post installation tasks:
			  • Set Windows PowerShell execution policy
			  • Enable Windows PowerShell remoting
			  • Enable Remote Desktop Protocol and Firewall rule
			  • Join the domain
			• 1.4-Install roles and features using default settings, rebooting as needed
			  • Hyper-V (plus management tools)
			  • Failover clustering (plus management tools)

2	Initial Network Configuration	All Nodes	• 2.1-Disable unused and disconnected interfaces and rename active connections (static IP addresses on all interfaces)
3	Initial Storage Configuration	Single Node	• 3.1-Present all shared storage to relevant nodes • 3.2-For multipath scenarios, install and configure multipath I/O (MPIO) as necessary

4	Failover Cluster Setup	Single Node	• 4.1-Run through the Cluster Validation Wizard
			• 4.2-Address any indicated warnings and/or errors
			• 4.3-Complete the Create Cluster Wizard (setting name and IP address but do not add eligible storage)
			• 4.4-Create a witness disk
			• 4.5-Create a virtual machine storage disk
			• 4.6-Add the virtual machine storage disk to cluster shared volumes
			• 4.7-Add folders to the cluster shared volume:
			  • C:\ClusterStorage\Volume1\VHDdisks\
			  • C:\ClusterStorage\Volume1\VHDsettings\
			• 4.8-Configure quorum settings
			• 4.9-Configure cluster networks to prioritize traffic

5	Hyper-V Configuration	All Nodes	• 5.1-Create the virtual switch
			• 5.2-Change default file locations, mapping to CSV volumes:
			  • C:\ClusteredStroage\Volume1\VHDfiles\
			  • C:\ClusterStorage\Volume1\VHDsettings\

6	Cloud Validation	Single Node	• 6.1-Create a virtual machine, attaching an existing operating system VHD and tagging to the appropriate VLAN • 6.2-Test network connectivity from the virtual machine • 6.3-Perform a Live Migration • 6.4-Perfomr a quick migration

Step 1: Initial node configuration

In step 1, you will perform the following steps on all nodes of the Hyper-V cluster:

- 1.1 Upgrade the machine to the latest BIOS release and enable BIOS settings for Hyper-V and SR-IOV.
- 1.2 Perform a clean operating system installation.
- 1.3 Perform post-installation tasks.
- 1.4 Install roles and features using the default settings.

1.1 Enable BIOS settings required for Hyper-V for SR-IOV

You will need to enable virtualization support in the BIOS of each cluster member prior to installing the Hyper-V server role. The procedure for enabling processor virtualization support will vary with your processors' make and model and the system BIOS. In addition, if you choose to enable SR-IOV, this capability will need to be enabled in the system BIOS. Please refer to your hardware documentation for the appropriate procedures. In addition, make sure to upgrade your servers with their latest BIOS revision.

1.2 Perform a clean operating system installation

Install Windows Server 2012 using the Full Installation option.

1.3 Perform post-installation tasks

There are several tasks you need to complete on each node after the operating system installation is complete. These include:

- Join each node to the domain
- Enable remote access to each node via the Remote Desktop Protocol.
- Set the Windows PowerShell execution policy.
- Enable Windows PowerShell remoting.

Perform the following steps to join each node to the domain:

1. Press the **Windows Key** on the keyboard and then press **R**. Type **Control Panel** and then click **OK**.
2. In the **Control Panel** window, click **System and Security**, and then click **System**.
3. In the **System** window under **Computer name, domain, and workgroup settings**, click **Change settings**.
4. In the **System Properties** dialog box, click **Change**.
5. Under **Member of**, click **Domain**, type the name of the domain, and then click **OK**.

Run the following Windows PowerShell commands on each node to enable remote access using the Remote Desktop Protocol, to enable PowerShell execution policy and enable PowerShell Remoting:

```
(Get-WmiObject Win32_TerminalServiceSetting -Namespace
root\cimv2\terminalservices).SetAllowTsConnections(1,1)

Set-ExecutionPolicy Unrestricted –Force

Enable-PSRemoting –Force
```

1.4 Install roles and features using the default settings

The following roles and features will be installed on each node of the cluster:

- Hyper-V and Hyper-V management Tools
- Failover cluster and failover cluster management tools

Perform the following steps on each node in the cluster to install the required roles and features:

1. In **Server Manager**, click **Dashboard** in the console tree.
2. In **Welcome to Server Manager**, click **2 Add roles and features**, and then click **Next**.
3. On the **Before You Begin** page of the **Add Roles and Features Wizard**, click **Next**.
4. On the **Installation Type** page, click **Next**.
5. On the **Server Selection** page, click **Next**.
6. On the **Server Roles** page, select **Hyper-V** from the **Roles** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Click **Next**.
7. On the **Features** page, select **Failover Clustering** from the **Features** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Click Next.

   Note
   If you plan to use Multipath I/O for your storage solution, select the Multipath I/O feature while performing step 7.
8. On the **Hyper-V** page, click **Next**.
9. On the **Virtual Switches** page, click **Next**.
10. On the **Migration** page, click **Next**.
11. On the **Default Stores** page, click **Next**.
12. On the **Confirmation** page, put a checkmark in the **Restart the destination server automatically if required** checkbox and then in the **Add Roles and Features** dialog box click **Yes**, then click **Install**.
13. On the **Installation progress** page, click **Close** after the installation has succeeded.
14. Restart the computer. This process might require restarting the computer twice. If so, the installer will trigger the multiple restarts automatically.

After you restart the server, open **Server Manager** and confirm that the installation completed successfully. Click **Close** on the **Installation Progress** page.

Step 2: Initial network configuration

The network configuration on each node in the cluster needs to be configured to support the non-converged networking scenario where all traffic types move through their own dedicated network adapters. You will perform the following procedures on each of the nodes in the cluster to complete the initial network configuration:

- 2.1 Disable unused and disconnected interfaces and rename active connections.

2.1 Disable unused and disconnected interfaces and rename active connections

You can simplify the configuration and avoid errors when running the wizards and running PowerShell commands by disabling all network interfaces that are either unused or disconnected. You can disable these network interfaces in the **Network Connections** window.

For the remaining network adapters, do the following:

1. Connect them to the network switch ports.

2. Configure appropriate IP addressing information for each network adapter based on your network addressing scheme for each traffic type. Make sure that each traffic type is assigned to a different network ID (subnet ID).
3. To help you more easily recognize the active network adapters, rename them with names that indicate their use or their connection to the intranet or Internet (for example, **ManagementNet** and **LiveMigrationNet** and **ClusterNet** and **TenantNet**). You can do this in the **Network Connections** window.

Note
Configure a DNS server and default gateway address only on the management interface adapter.

Step 3: Initial storage configuration

With the initial cluster node configuration complete, you are ready to perform initial storage configuration tasks on all nodes of the cluster. Initial storage configuration tasks include:

- 3.1 Present all shared storage to relevant nodes.
- 3.2 Install and configure MPIO as necessary for multipath scenarios.

3.1 Present all shared storage to relevant nodes

Connect the host bus adapter (HBA) fiber optic cables to a FC hub or switch that is connected to the storage device. Each cluster node should have two HBAs in them if high availability of storage access is required.

Configure the storage device with the appropriate RAID settings and volumes (LUNs) so that the storage on the device is available from the Disk Management console of the Computer Management snap-in of each cluster member computer.

For the first computer that is attached to the storage, create the following from this storage space:

- A 1 GB NTFS volume that may be used for the cluster witness disk.
- An NTFS volume with an appropriate amount of space that will be used to store the virtual machine folders and files of the Hyper-V cluster.

3.2 Install and configure MPIO as necessary for multipath scenarios

If you have multiple data paths to storage (for example, two SAS cards) make sure to install the Microsoft® Multipath I/O (MPIO) on each node. This step might require you to restart the system. For more information about MPIO, see What's New in Microsoft Multipath I/O.

Step 4: Failover cluster setup

You are now ready to complete the failover cluster settings. Failover cluster setup includes the following steps:

- 4.1 Run through the Cluster Validation Wizard.
- 4.2 Address any indicated warnings and/or errors.

- 4.3 Complete the Create Failover Cluster Wizard.
- 4.4 Create the witness virtual disk.
- 4.5 Create the virtual machine storage virtual disk.
- 4.6 Add the virtual machine storage virtual disk and Witness disk to Cluster Shared Volumes.
- 4.7 Add folders to the cluster shared volume.
- 4.8 Configure Quorum Settings.
- 4.9 Configure cluster networks to prioritize traffic.

4.1 Run through the Cluster Validation Wizard

The Cluster Validation Wizard will query multiple components in the intended cluster hosts and confirm that the hardware and software is ready to support failover clustering. On one of the nodes in the server cluster, perform the following steps to run the Cluster Validation Wizard:

1. In the **Server Manager**, click **Tools**, and then click **Failover Cluster Manager**.
2. In the **Failover Cluster Manager** console, in the **Management** section, click **Validate Configuration**.
3. On the **Before You Begin** page of the **Validate a Configuration Wizard**, click **Next**.
4. On the **Select Servers or a Cluster** page, type the name of the local server, and then click **Add**. After the name appears in the **Selected servers** list, type the name of another Hyper-V cluster member computer, and then click **Add**. Repeat this step for all computers in the Hyper-V cluster. When all of the servers of the Hyper-V cluster appear in the **Selected servers** list, click **Next**.
5. On the **Testing Options** page, click **Next**.
6. On the **Confirmation** page, click **Next**. The time to complete the validation process will vary with the number of nodes in the cluster and can take some time to complete.
7. On the **Summary** page, the summary text will indicate that the configuration is suitable for clustering. Confirm that there is a checkmark in the **Create the cluster now using the validated nodes...** checkbox.

4.2 Address any indicated warnings and/or errors

Click the **Reports** button to see the results of the Cluster Validation. Address any issues that have led to cluster validation failure. After correcting the problems, run the Cluster Validation Wizard again. After the cluster passes validation, then proceed to the next step. Note that you may see errors regarding disk storage. You may see this if you haven't yet initialized the disks. Click **Finish**.

4.3 Complete the Create Failover Cluster Wizard

After passing cluster validation, you are ready to complete the cluster configuration.

Perform the following steps to complete the cluster configuration:

1. On the **Before You Begin** page of the **Create Cluster Wizard**, click **Next**.

2. On the **Access Point for Administering the Cluster** page, enter a valid NetBIOS name for the cluster, and then select the network you want the cluster on and then type in a static IP address for the cluster object, and then click **Next**. In this example, the network you would select is the Management Network. Unselect all other networks that appear here.
3. On the **Confirmation** page, clear **Add all eligible storage to the cluster** checkbox and then click **Next**.
4. On the **Creating New Cluster** page you will see a progress bar as the cluster is created.
5. On the **Summary** page, click **Finish**.
6. In the console tree of the **Failover Cluster Manager** snap-in, open the **Networks** node under the cluster name.
7. Right-click the cluster network that corresponds to the management network adapter network ID (subnet), and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is *not* selected and that **Allow clients to connect through this network** is enabled. In the **Name** text box, enter a friendly name for this network (for example, ManagmentNet), and then click **OK**.
8. Right-click the cluster network that corresponds to the Cluster network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is not enabled. In the **Name** text box, enter a friendly name for this network (for example, ClusterNet), and then click **OK**.
9. Right-click the cluster network that corresponds to the live migration network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is not enabled. In the **Name** text box, enter a friendly name for this network (for example, LiveMigrationNet), and then click **OK**.

4.4 Create the witness disk

You will need a disk of at least 1 GB and a volume on it formatted as NTFS to use it as a witness disk. Later you will use this disk when you configure the quorum model.

4.5 Create the virtual machine storage disk

You will next need to a disk that you will place the virtual machine disk and configuration files on. This disk can be of any size but should be large enough to support the number of virtual machines you want to run on the cluster. You can use multiples disks if you like. This disk must have volumes on it that are formatted as NTFS so that they can be placed into a cluster shared volume.

4.6 Add the virtual machine storage disk and Witness disk to Cluster Shared Volumes

The disk you created for virtual machine storage is now ready to be added to a Cluster Shared Volume. Perform the following steps to add the virtual disk to a Cluster Shared Volume.

1. In the **Failover Cluster Manager**, in the left pane of the console, expand the **Storage** node and click **Disks**. In the middle pane of the console, in the **Disks** section, right click the disk you created in the previous step and then click **Add to Cluster Shared Volumes**.
2. Repeat step 1 to add the witness disk to a cluster shared volume.

4.7 Add folders to the cluster shared volume

Now you need to create the folders on the disk located on the Cluster Shared Volume to store the virtual machine files and the virtual machine data files.

Perform the following steps to create the folders that will store the running VMs of the Hyper-V cluster:

1. Open **Windows Explorer** and navigate to the C: drive and then double-click **Cluster Storage** and then double-click **Volume 1**.
2. Create two folders in **Volume 1**. One of the folders will contain the .vhd files for the virtual machines (for example, VHDdisks) and one folder will contain the virtual machine configuration files (for example, VHDsettings)

4.8 Configure Quorum Settings

Perform the following steps to configure quorum settings for the cluster:

1. In the left pane of the **Failover Cluster Manager** console, right click on the name of the cluster and click **More Actions** and click **Configure Cluster Quorum Settings**.
2. On the **Before You Begin** page, click **Next**.
3. On the **Quorum Configuration Option** page, select **Use typical settings (recommended)** and click **Next**.
4. On the **Confirmation** page, click **Next**.

4.9 Configure cluster networks to prioritize traffic

The cluster will use the network with the lowest metric for CSV traffic and the second lowest metric for live migration. Windows PowerShell® is the only method available to prescriptively specify the CSV network.

Run the following Windows PowerShell commands on one node of the failover cluster to set the metric for the cluster network traffic, set the metric for the live migration network traffic and set the metric for the management network traffic:

```
(Get-ClusterNetwork "ClusterNet" ).Metric = 100

(Get-ClusterNetwork "LiveMigrationNet" ).Metric = 500

(Get-ClusterNetwork "ManagementNet" ).Metric = 1000.
```

Step 5: Configure Hyper-V settings

To finalize the Hyper-V configuration, you will need to:

- 5.1 Create the Hyper-V virtual switch

- 5.2 Change default file locations for virtual machine files.

5.1 Create the Hyper-V virtual switch

On *each Hyper-V cluster member*, perform the following steps to create the Hyper-V virtual switch that will be used by the tenant virtual machines:

1. Right-click the network icon in the notification area of the desktop, and then click **Open Network and Sharing Center**.
2. From the **Network and Sharing Center** window, click **Change adapter settings**.
3. In the **Network Connections** window, double-click the adapter with the name of the network adapter that is attached to the tenant subnet (for example, TenantNet), and then click **Details**.
4. In the **Network Connections Details** window, note the value of the **Description** field, and then click **Close**. You will need this information to determine which physical network adapter to bind to the virtual switch.
5. In the console tree of the **Hyper-V Manager**, right-click the name of the server, and then click **Virtual Switch Manager**.
6. In **Create virtual switch**, click **External**, and then click **Create virtual switch**.
7. In **Name**, enter a name for the virtual network to indicate that it is connected to the tenant subnet (for example, **TenantNetSwitch**).
8. On **External**, select the description of the network adapter attached to the Tenant subnet, as noted in step 7, select **Enable Single-Root I/O Virtualization (SR-IOV)**, and then click **OK**.

   Note
   If your hardware does not support SR-IOV or if SR-IOV is not enabled in the BIOS, the option will not be available. You can use the Get-NetAdapterSriov command to help make this assessment http://technet.microsoft.com/en-us/library/jj130915.aspx
9. When prompted with the **Apply Networking Changes** window, click **Yes**.

   Note
   If you are performing these steps over a remote desktop connection, you will temporarily lose connectivity.

5.2 Change default file locations for virtual machine files

On *each Hyper-V cluster member*, perform the following steps to change the default file locations for virtual machine files:

1. In **Server Manager**, click **Tools**, then click **Hyper-V Manager**.
2. From the console tree of the **Hyper-V Manager**, right-click the name of the Hyper-V server, and then click **Hyper-V Settings**.
3. In the **Hyper-V Settings** dialog box, click **Virtual Hard Disks** under **Server**, type the path to the folder where the virtual hard disk files are stored or use the **Browse** button in **Specify the default folder to store virtual hard disk files**, and then click **Apply**.

4. Click **Virtual Machines under Server**, type the file folder location or use the **Browse** button in **Specify the default folder to store virtual machine configuration files**, and then click **OK**

Step 6: Cloud validation

To verify the configuration of your cloud environment, perform the following operations.

- 6.1 Create a new virtual machine.
- 6.2 Test network connectivity from the virtual machine.
- 6.3 Perform a live migration.
- 6.4 Perform a quick migration.

6.1 Create a new virtual machine

To create a new virtual machine in the cluster environment, perform the following steps.

1. **Open Failover Cluster Manager**, click **Roles** under the cluster name, click **Virtual Machines** under the **Actions** pane, and then click **New Virtual Machine**.
2. On the **New Virtual Machine** page, select the cluster node where you want to create the virtual machine, and then click **OK**.
3. On the **Before you Begin** page of the **New Virtual Machine Wizard**, click **Next**.
4. On the **Specify Name and Location** page, enter a friendly name for this virtual machine and then click **Next**.
5. On the **Assign Memory** page, enter the amount of memory that will be used for this virtual machine (minimum for this lab is 1024 MB RAM) and then click **Next**.
6. On the **Configuring Networking** page, select the **TenantNetSwitch** and then click **Next**.
7. On the **Connect Virtual Hard Disk** page, leave the default options selected and click **Next**.
8. On the **Installation Options** page, select **Install an operating system from a boot CD/DVD-ROM** and then select the location where the CD/DVD is located. If you are installing the new operating system based on an ISO file, make sure to select the option Image file (.iso) and browse for the file location. After you select the appropriate option for your scenario, click **Next**.
9. On the **Completing the New Virtual Machine Wizard** page, review the options, and then click **Finish**.
10. The virtual machine creation process starts. After it is finished, you will see the **Summary** page, where you can access the report created by the wizard. If the virtual machine was created successfully, click **Finish**.

At this point your virtual machine is created and you should use the Failover Cluster Manager to start the virtual machine and perform the operating system installation according to the operating system that you choose. For the purpose of this validation, the guest operating system can be any Windows Server version.

6.2 Test network connectivity from the virtual machine

Once you finish installing the operating system in the virtual machine you should log on and verify if this virtual machine was able to obtain IP address from the enterprise network. Assuming that in this network you have a DHCP server, this virtual machine should be able to obtain the IP address. To perform the basic network connectivity test use the following approach.

- Use `ping` command for a reachable IP address in the same subnet.
- Use `ping` command for the same destination but now using the full qualified domain name for the destination host. The goal here is to test basic name resolution.

Note

You may need to open Windows Firewall with Advanced Security and create a new rule to allow Internet Control Message Protocol (ICMP) before performing the previous tests. This may be true for other hosts you want to ping − confirm that the host-based firewall on the target allows for ICMP Echo Requests.

After you confirm that this basic test is working properly, leave a command prompt window open and enter the command ping <Destination_IP_Address_or_FQDN> -t. The goal here is to have a continuous test while you perform the live migration to the second node.

Note

If you prefer to work with PowerShell, instead of the ping command you can use the **Test-Connection** command. This cmdlet provides you a number of connectivity testing options that exceed what is available with the simple ping command.

6.3 Perform a live migration

To perform a live migration of this virtual machine from the current cluster node to the other node in the cluster, perform the following steps.

1. In the **Failover Cluster Manager**, click **Roles** under the cluster name. On the Roles pane, right click the virtual machine that you created, click **Move**, click **Live Migration**, and then click **Select Node**.
2. On the **Move Virtual Machine** page, select the node that you want to move the virtual machine to and click **OK**.

You will notice in the **Status** column when the live migration starts, it will take some time for the **Information** column to update the current state of the migration. While the migration is taking place you can go back to the virtual machine that has the ping running and observe if there is any packet loss.

6.4 Perform a quick migration

To perform the quick migration of this virtual machine from the current node to the other one, perform the following steps.

1. On the **Failover Cluster Manager**, click **Roles** under the cluster name. In the **Roles** pane, right-click the virtual machine that you created, click **Move**, click **Quick Migration** and then click **Select Node**.

2. On the **Move Virtual Machine** window, select the node that you want to move the virtual machine to, and then click **OK**.

You will notice in the status that the quick migration will start faster than the live migration did. While the migration is taking place you can go back to the virtual machine that has the ping running and observe if there is any packet loss.

Building Your Cloud Infrastructure: Converged Data Center with File Server Storage

This document contains the instructions to create a private or public cloud configuration that uses:

- Two subnets - one for cloud infrastructure traffic (live migration, cluster, storage and management) one for tenant traffic.
- NIC Teaming for network bandwidth aggregation and failover for the infrastructure and tenant subnet.
- A dedicated file server storage cluster that hosts virtual machine VHDX and configuration files.
- A dedicated Hyper-V compute cluster that runs the virtual machine workloads.

The design pattern discussed in this document is one of three design patterns we suggest for building the core cloud network, compute and storage infrastructure. For information about the other two cloud infrastructure design patterns, please see:

- Building Your Cloud Infrastructure: Non-Converged Data Center Configuration
- Building Your Cloud Infrastructure: Converged Data Center without Dedicated Storage Nodes

Design Considerations and Requirements for the Converged Data Center with File Server Storage Pattern

The Converged Data Center with File Server Storage cloud infrastructure design pattern focuses on the following key requirements in the areas of networking, compute and storage:

Networking

- You require that cloud infrastructure traffic be physically separated from cloud tenant traffic. The requirement is met by creating separate NIC teams for infrastructure and tenant traffic and connecting them to different subnets/segments.
- You require that infrastructure traffic (i.e. live migration, cluster, storage, management) all receive guaranteed levels of bandwidth. The requirement is met by using Windows QoS policies on the parent Hyper-V partition..

- You require that tenant traffic from different tenants receive guaranteed levels of bandwidth. The requirement is met by using Hyper-V virtual switch QoS policies.
- You require the highest networking performance possible to support hosting Virtual Machines and VHD/X files on a file server using the SMB 3.0 protocol. The requirement is met by installing and enabling Remote Direct Memory Access (Remote DMA or RDMA) network adapters on both the Hyper-V Server cluster and the File server cluster.

Storage

- You require the ability to scale and manage storage separately from the compute infrastructure. This requirement can be met by creating a dedicated storage cluster that will host the VHDX and virtual machine configuration files. The Hyper-V compute cluster will connect to the file server cluster using SMB 3.0 to connect to file shares on the storage cluster. The file server cluster will be configured to use the new Windows Server 2012 Scale-out File Server feature.
- You require a low cost storage option. This requirement is met by using Serial Attached SCSI (SAS) disks in shared JBOD enclosures managed through Storage Spaces. Alternatively, each member of the file server failover cluster can connect to iSCSI, Fibre Channel or Fibre Channel over Ethernet. Only the SAS scenario is described in this document.
- You require a resilient storage solution. This requirement is met by using two file servers configured as a failover cluster, with well-connected (shared JBODs) storage so that all members of the file server failover cluster are directly connected to storage with Storage Spaces configured as a mirrored space to guarantee against data loss in the case of disk failures. In addition, each member of the file server failover cluster is able to access the shared storage by using Windows Server 2012 Failover Clustering and Cluster Shared Volumes Version 2 (CSV v2) volumes to store virtual machine files and metadata.

Compute

- You require the ability to scale your compute infrastructure separately from your storage infrastructure. This requirement is met by creating a dedicated Hyper-V compute cluster that connects to remote file server storage for virtual machines and virtual machine configuration files. Local disks on the compute nodes are only used for the boot partition but not for the virtual machines.
- You require that virtual machines will be continuously available and resilient to hardware failures. This requirement can be met by using Windows Server 2012 Failover Clustering together with the Hyper-V Server Role.
- You require the highest number of virtual machines possible per host server (i.e. increased density). This requirement is met by using processor offload technologies, such as Remote Direct Memory Access (RDMA), Receive Side Scaling, Receive Side Coalescing (RSC), and Datacenter Bridging (DCB).

Overview

A Windows Server® 2012 cloud infrastructure described in this document is a high-performing and highly available Hyper-V cluster that hosts virtual machines that can be managed to create private or public clouds connected to a converged 10Gb Ethernet network, and using dedicated file servers as the storage nodes. This document explains how to configure the basic building blocks for such a cloud. It does not cover the System Center or other management software aspects of deployments; the focus is on configuring the core Windows Server computers that are used to build cloud infrastructure.

For background information on creating clouds using Windows Server 2012, see Building Infrastructure as a Service Clouds using Windows Server "8".

This cloud configuration consists of the following:

- Multiple computers in a dedicated Hyper-V compute cluster.

  A Hyper-V cluster is created using the Windows Server 2012 Failover Cluster feature. The Windows Server 2012 Failover Clustering feature set is tightly integrated with the Hyper-V server role and enables a high level of availability from a compute and networking perspective. In addition, Windows Server 2012 Failover Clustering enhances virtual machine mobility which is critical in a cloud environment. The Hyper-V cluster is a dedicated compute cluster and does not host storage for virtual machines and virtual machine configuration files.

- Multiple computers in a dedicated Scale-out File Server storage cluster.

  A File Server cluster is created using the Windows Server 2012 Failover Cluster feature. Windows Server 2012 includes a new file server capability known as "Scale-out File Server for applications" that enables you to store virtual machine and virtual machine configuration files in a file share and make these files continuously available. When you separate the file server cluster from the compute cluster you are able to scale compute and storage resources independently.

- A converged networking infrastructure that supports physical segmentation of infrastructure and tenant traffic.

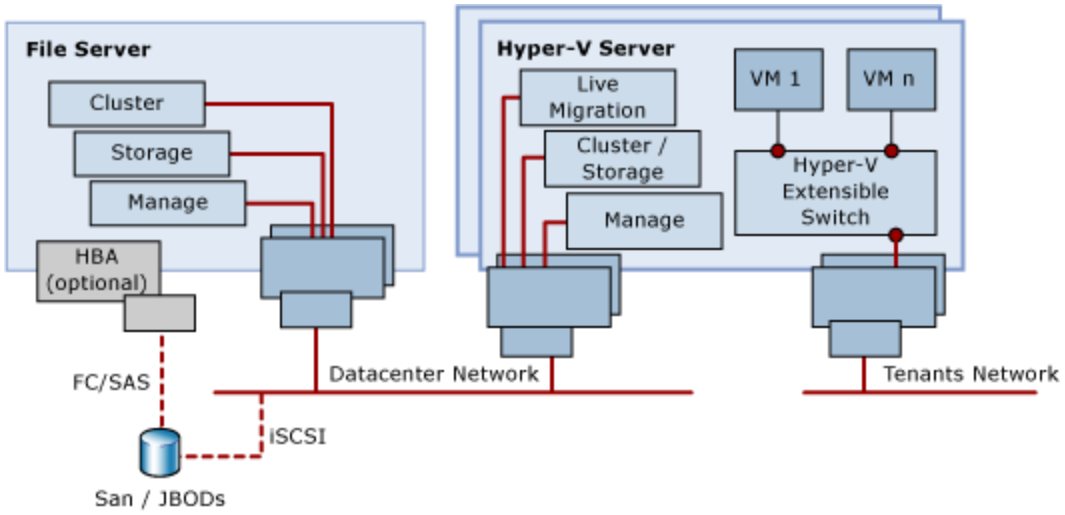
  Each computer in the Hyper-V failover cluster must have at least two network adapters so that one adapter can host the cloud infrastructure traffic and one adapter can support tenant traffic. If resiliency against NIC failures is required, then you can add additional network adapters on each of the networks, and team them using Windows Server 2012 Load Balancing and Failover (LBFO) NIC Teaming. The NICs can be 10 GbE or 1 GbE network adapters. These NICs will be used for live migration, cluster, storage, management (together referred to as "infrastructure" traffic) and tenant traffic.

- The appropriate networking hardware (e.g. Ethernet switches, cables, etc.) to connect all of the computers in the Hyper-V cluster to each other and to a larger network from which the hosted virtual machines are available.

Figure 1 provides a high-level view of the scenario layout. Key elements of the configuration include:

- A File Server cluster that hosts the virtual hard disks and virtual machine configuration files
- The File Server cluster is connected only to the infrastructure network

- The File Server cluster is connected to block storage either through HBAs or over a 10 GB Ethernet network (as in the case of iSCSI or Fibre Channel of Ethernet [FCoE])
- A Hyper-V compute cluster that hosts the virtual machine workloads.
- The Hyper-V compute cluster is connected to the datacenter network and the tenant network using teamed network adapters.
- Cloud infrastructure traffic flows to and from the host-based 10GbE network adapter
- Tenant network traffic to and from the virtual machines flows through the Hyper-V virtual switch which is bound to the Tenant Network NIC team.



Note

Although this configuration uses SAS storage on the file server cluster, you can easily choose to use other types of storage, such as iSCSI or Fibre Channel-based SAN storage. You can find more information about storage configuration for a non-SAS scenario in the document Building Your Cloud Infrastructure: Non-Converged Enterprise Configuration, which describes how to configure the SAN storage.

Note

At least one Active Directory Domain Services (AD DS) domain controller is needed for centralized security and management of the cluster member computers (not shown). It must be reachable by all of the cluster member computers, including the members of the shared storage cluster. DNS services are also required and are not depicted.

This configuration highlights the following technologies and features of Windows Server 2012:

- **Load Balancing and Failover (LBFO)**: Load Balancing and Failover logically combines multiple network adapters to provide bandwidth aggregation and traffic failover to prevent connectivity loss in the event of a network component failure. Load Balancing with Failover is also known as NIC Teaming in Windows Server 2012.
- **Windows Server Quality of Service (QoS)**: Windows Server 2012 includes improved QoS features that lets you manage bandwidth and provide predictable network performance to traffic to and from the host operating system.

- **Data Center Bridging (DCB)**: DCB provides hardware-based bandwidth allocation to a specific type of traffic and enhances Ethernet transport reliability with the use of priority-based flow control. Hardware-based bandwidth allocation is essential if traffic bypasses the operating system and is offloaded to a converged network adapter, which might support Internet Small Computer System Interface (iSCSI), Remote Direct Memory Access (RDMA) over Converged Ethernet, or Fiber Channel over Ethernet (FCoE).
- **Storage Spaces**: Storage Spaces makes it possible for you to create cost-effective disk pools that present themselves as a single mass storage location on which virtual disks or volumes can created and formatted.

The following sections describe how to set up this cloud configuration using UI-based tools and Windows PowerShell.

After the cloud is built, you can validate the configuration by doing the following:

- Install and configure virtual machines
- Migrate running virtual machines between servers in the Hyper-V cluster (live migration)

Install and configure the Converged Data Center with File Server Storage cloud infrastructure

In this section we will cover step by step how to configure the cloud infrastructure compute and storage scale units described in this document.

Creating this cloud infrastructure configuration consists of the following steps:

- Step 1: Initial node configuration
- Step 2: Initial network configuration
- Step 3: Initial storage configuration
- Step 4: File Server failover cluster setup
- Step 5: Hyper-V failover cluster setup
- Step 6: Configure Hyper-V settings
- Step 7: Cloud validation

The following table summarizes the steps that this document describes:

Step	Task	Target	Tasks
1	Initial Node Configuration for Compute and Storage Clusters	All Nodes	• 1.1-Enable BIOS settings required for Hyper-V on the nodes in the Hyper-V cluster • 1.2-Perform a clean operating system installation on all nodes in the Hyper-V and File Server clusters • 1.3-Perform post

			installation tasks on all nodes in the Hyper-V and File Server clusters: • Set Windows PowerShell execution policy • Enable Windows PowerShell remoting • Enable Remote Desktop Protocol and Firewall rules • Join the domain • 1.4-Install roles and features using default settings, rebooting as needed on the Hyper-V failover cluster: • Hyper-V (plus management tools) • Data Center Bridging (DCB) • Failover clustering (plus management tools) • 1.5-Install roles and features using default settings, rebooting as needed on the File Server failover cluster: • Failover clustering (plus management tools) • File Server Role • File Sharing and storage management tools
2	Initial Network Configuration	All Nodes	• 2.1-Disable unused and disconnected interfaces and rename active connections • 2.2-Create the infrastructure network

			NIC team and the tenant NIC team on each member of the Hyper-V Cluster and assign IP addressing information. • 2.3-Create the infrastructure NIC team on each member of the file server cluster and assign IP addressing information • 2.4-Configure QoS settings for infrastructure traffic
3	Initial Storage Configuration	Single Node	• 3.1-Present all shared storage to relevant nodes • 3.2-For multipath scenarios, install and configure multipath I/O (MPIO) as necessary • 3.3-All shared disks: Wipe, bring online and initialize
4	File Server Failover Cluster Setup	Single Node	• 4.1-Run through the Cluster Validation Wizard • 4.2-Address any indicated warnings and/or errors • 4.3-Complete the Create Cluster Wizard (setting name and IP but do not add eligible storage) • 4.4-Create the cluster storage pool • 4.5-Create the quorum virtual disk • 4.6-Create the virtual machine storage virtual disk

			• 4.7-Add the virtual machine storage virtual disk to Cluster Shared Volumes • 4.8-Add folders to the cluster shared volume • 4.9-Configure Quorum Settings • 4.10-Add the Scale-Out File Server for Applications Role
5	Hyper-V Failover Cluster Setup	Single Node	• 5.1-Run through the Cluster Validation Wizard • 5.2-Address any indicated warnings and/or errors • 5.3-Complete the Create Cluster Wizard • 5.4-Verify cluster quorum configuration and modify as necessary • 5.5-Configure cluster network metrics
6	File Shares Setup	Single Node	• 6.1-Create Shares and Configure Hyper-V Settings using a Script • 6.2-Configure Kerberos Constrained Delegation
7	Cloud Validation	Single Node	• 7.1-Create the TenantNetSwitch • 7.2-Create a New Virtual machine • 7.3-Test network connectivity from the virtual machine • 7.4-Perform a Live Migration • 7.5-Perform a quick migration

Step 1: Initial node configuration

In step 1, you will perform the following steps on all nodes of the Hyper-V and File Server clusters:

- 1.1 Enable BIOS settings required for Hyper-V on the nodes in the Hyper-V cluster.
- 1.2 Perform a clean operating system installation on all nodes in the Hyper-V and File Server clusters.
- 1.3 Perform post-installation tasks on all nodes in the Hyper-V and File Server clusters.
- 1.4 Install roles and features using the default settings on the Hyper-V failover cluster.
- 1.5 Install roles and features using the default settings on the filer server failover cluster

1.1 Enable BIOS settings required for Hyper-V on the Nodes in the Hyper-V Cluster

You will need to enable virtualization support in the BIOS of each cluster member prior to installing the Hyper-V server role. The procedure for enabling processor virtualization support will vary with your processors' make and model and the system BIOS. Please refer to your hardware documentation for the appropriate procedures. In addition, confirm that all systems have the latest BIOS updates installed.

1.2 Perform a clean operating system installation on all nodes in the Hyper-V and File Server Clusters

Install Windows Server 2012 using the Full Installation option.

1.3 Perform post-installation tasks on all nodes in the Hyper-V and File Server Clusters

There are several tasks you need to complete on each node of the compute and file server clusters after the operating system installation is complete. These include:

- Join each node to the domain
- Enable remote access to each node via the Remote Desktop Protocol.
- Set the Windows PowerShell execution policy.
- Enable Windows PowerShell remoting.

Perform the following steps to join each node to the domain:

1. Press the Windows Key on the keyboard and then press R. Type Control Panel and then click OK.
2. In the Control Panel window, click System and Security, and then click System.
3. In the System window under Computer name, domain, and workgroup settings, click Change settings.
4. In the System Properties dialog box, click Change.
5. Under Member of, click Domain, type the name of the domain, and then click OK.

Run the following Windows PowerShell commands on each node of the compute and file server clusters to enable remote access using the Remote Desktop Protocol (RDP), to enable PowerShell execution policy and enable PowerShell Remoting:

```
(Get-WmiObject Win32_TerminalServiceSetting -Namespace
root\cimv2\terminalservices).SetAllowTsConnections(1,1)

Set-ExecutionPolicy Unrestricted –Force

Enable-PSRemoting –Force
```

1.4 Install roles and features using the default settings on the Hyper-V Failover Cluster

The following roles and features will be installed on *each node* of the Hyper-V compute cluster:

- Hyper-V and Hyper-V management Tools
- Data Center Bridging (DCB)
- Failover cluster and failover cluster management tools

Perform the following steps on *each node* in the cluster to install the required roles and features:

1. In **Server Manager**, click **Dashboard** in the console tree.
2. In **Welcome to Server Manager**, click **2 Add roles and features**, and then click **Next**.
3. On the **Before You Begin** page of the **Add Roles and Features Wizard**, click **Next**.
4. On the **Installation Type** page, click **Next**.
5. On the **Server Selection** page, click **Next**.
6. On the **Server Roles** page, select **Hyper-V** from the **Roles** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Click **Next**.
7. On the **Features** page, select **Data Center Bridging and Failover Clustering** from the **Features** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Click **Next**.

   Note
   If you plan to use Multipath I/O for your storage solution, select the **Multipath I/O** feature while performing step 7.
8. On the **Hyper-V** page, click **Next**.
9. On the **Virtual Switches** page, click **Next**.
10. On the **Migration** page, click **Next**.
11. On the **Default Stores** page, click **Next**.
12. On the **Confirmation** page, put a checkmark in the **Restart the destination server automatically if required** checkbox and then in the **Add Roles and Features** dialog box click **Yes**, then click **Install**.
13. On the **Installation progress** page, click **Close** after the installation has succeeded.
14. Restart the computer. This process might require restarting the computer twice. If so, the installer will trigger the multiple restarts automatically.

After you restart the server, open **Server Manager** and confirm that the installation completed successfully. Click **Close** on the **Installation Progress** page.

1.5 Install roles and features using the default settings on the File Server Failover Cluster

The following roles and features will be installed on each node of the file server failover cluster:

- Failover cluster and failover cluster management tools
- Datacenter Bridging (DCB)
- Storage management tools

Perform the following steps on each node in the file server failover cluster to install the required roles and features:

1. In **Server Manager**, click **Dashboard** in the console tree.
2. In **Welcome to Server Manager**, click **2 Add roles and features**, and then click **Next**.
3. On the **Before You Begin** page of the **Add Roles and Features Wizard**, click **Next**.
4. On the **Installation Type** page, click **Next**.
5. On the **Server Selection** page, click **Next**.
6. On the **Server Roles** page, expand the **File and Storage Services** node, then expand the **File and iSCSI Services** node and select **File Server**. Click **Next**.
7. On the **Features** page, select **Data Center Bridging and Failover Clustering** from the **Features** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Expand **Remote Server Administrator Tools** and then expand **Role Administration Tools. Expand File Services Tools**. Select **Share and Storage Management Tool**. Click **Next**.

   Note
   If you plan to use Multipath I/O for your storage solution, select the **Multipath I/O** feature while performing step 7.
8. On the **Confirmation** page, put a checkmark in the **Restart the destination server automatically if required** checkbox and then in the **Add Roles and Features** dialog box click **Yes**, then click **Install**.
9. On the **Installation progress** page, click **Close** after the installation has succeeded.
10. Restart the computer. This process might require restarting the computer twice. If so, the installer will trigger the multiple restarts automatically.

After you restart the server, open **Server Manager** and confirm that the installation completed successfully. Click **Close** on the **Installation Progress** page.

Step 2: Initial network configuration

The network configuration on each node in both the compute and file server clusters needs to be configured. The networking configuration on the compute cluster needs to be configured to support the converged networking scenario where all traffic, including infrastructure and tenant traffic, moves through the Hyper-V virtual switch. The network configuration on the file server

cluster will connect it to the infrastructure network. You will perform the following procedures to complete the initial networking configuration for the compute and file server clusters:

- 2.1 Disable unused and disconnected interfaces and rename active connections.
- 2.2 Create the infrastructure network NIC team and the tenant network NIC team on each member of the Hyper-V cluster.
- 2.3 Create the infrastructure network NIC team on each member of the file server cluster.
- 2.4 Configure QoS settings for infrastructure traffic

2.1 Disable unused and disconnected interfaces and rename active connections

You can simplify the configuration and avoid errors when running the wizards and running PowerShell commands by disabling all network interfaces that are either unused or disconnected. You can disable these network interfaces in the **Network Connections** window.

For the remaining network adapters for all servers in the compute and storage failover clusters, do the following:

1. Connect them to the appropriate network switch ports.
2. To help you more easily recognize the active network adapters, rename them with names that indicate their use or their connection to the intranet or Internet (for example, **HosterNet1** and **HosterNet2** for the infrastructure network NICs and **TenantNet1** and **TenantNet2** for the tenant network NICs). You can do this in the **Network Connections** window.

2.2 Create the infrastructure and the tenant networks NIC teams on each member of the Hyper-V cluster

Network Load Balancing and Failover (LBFO) enables bandwidth aggregation and network adapter failover to prevent connectivity loss in the event of a network card or port failure. This feature is commonly referred to as "NIC Teaming". In this scenario you will create one team that will be connected to the HosterNet subnet (which is the cloud infrastructure network).

To configure the network adapter teams by using **Server Manager**, do the following on each computer in the Hyper-V compute cluster:

Note

Some steps in the following procedure will temporarily interrupt network connectivity. We recommend that all servers be accessible over a keyboard, video, and mouse (KVM) switch so that you can check on the status of these machines if network connectivity is unavailable for more than five minutes.

1. From **Server Manager**, click **Local Server** in the console tree.
2. In **Properties**, click **Disabled**, which you'll find next to **Network adapter teaming**.
3. In the **NIC Teaming window**, click the name of the server computer in **Servers**.
4. In **Teams**, click **Tasks**, and then click **New Team**.
5. In the **New Team** window, in the **Team Name** text box, enter the name of the network adapter team for the infrastructure traffic subnet (example: **HosterNetTeam**).

6. In the **Member adapters** list select the two network adapters connected to the converged traffic subnet (in this example, **HosterNet1** and **HosterNet2**), and then click **OK**. Note that there may be a delay of several minutes before connectivity is restored after making this change. To ensure that you see the latest state of the configuration, right click your server name in the **Servers** section in the **NIC Teaming** window and click **Refresh Now**. There may be a delay before the connection displays as **Active**. You may need to refresh several times before seeing the status change.
7. Repeat the procedure to create a NIC Team for the tenant network NICs and give it an informative name, such as **TenantNetTeam**.
8. Close the **NIC Teaming** window.
9. Assign static IP addresses to your NIC teams.

Configure static IPv4 addressing information for the new network adapter team connected to the infrastructure and tenant traffic subnets (example: **HosterNetTeam** and **TenantNetTeam**). The IP addresses will be the ones that you will use when connecting to the host system for management purposes. You can configure the IP addressing information in the **Properties** of the team in the **Network Connections** window. You will see new adapters where the names of the teamed network adapters are the names you assigned in step 5. You will lose connectivity for a few moments after assigning the new IP addressing information.

Note

You might need to manually refresh the display of the **NIC Teaming** window to show the new team and there may be a delay in connectivity as the network adapter team is created. If you are managing this server remotely, you might temporarily lose connectivity to the server.

2.3 Create the infrastructure network NIC team on each member of the File Server cluster

You now are ready to team the network adapters on the servers in the file server failover cluster. The file server failover cluster is connected only to the infrastructure network, so you will create a single team on each server in the failover cluster..

To configure the network adapter teams by using **Server Manager**, do the following on *each computer in the file server failover cluster*:

Note

Several steps in the following procedure will temporarily interrupt network connectivity. We recommend that all servers be accessible over a keyboard, video, and mouse (KVM) switch so that you can check on the status of these machines if network connectivity is unavailable for more than five minutes.

1. From **Server Manager**, click **Local Server** in the console tree.
2. In **Properties**, click **Disabled**, which you'll find next to **Network adapter teaming**.
3. In the **NIC Teaming** window, click the name of the server computer in **Servers**.
4. In **Teams**, click **Tasks**, and then click **New Team**.

5. In the **New Team** window, in the **Team Name** text box, enter the name of the network adapter team for the converged traffic subnet (example: **HosterNetTeam**).
6. In the **Member** adapters list select the two network adapters connected to the converged traffic subnet (in this example, **HosterNet1** and **HosterNet2**), and then click **OK**. Note that there may be a delay of several minutes before connectivity is restored after making this change. To ensure that you see the latest state of the configuration, right click your server name in the **Servers** section in the **NIC Teaming** window and click **Refresh Now**. There may be a delay before the connection displays as **Active**. You may need to refresh several times before seeing the status change.
7. Close the **NIC Teaming** window.

Configure a static IPv4 addressing configuration for the new network adapter team connected to the infrastructure traffic subnet (example: **HosterNet Team**). This IP address is the one that you will use when connecting to the host system for management purposes. You can do this in the **Properties** of the team in the **Network Connections** window. You will see a new adapter where the name of the teamed network adapter is the name you assigned in step 5. You will lose connectivity for a few moments after assigning the new IP addressing information.

Note

You might need to manually refresh the display of the **NIC Teaming** window to show the new team and there may be a delay in connectivity as the network adapter team is created. If you are managing this server remotely, you might temporarily lose connectivity to the server.

2.4 Configure QoS settings for infrastructure traffic

If both your 10 GbE network adapter and 10 GbE-capable switch support Data Center Bridging and you want to use DCB for QoS offload you can take advantage of Windows Server 2012 support for Data Center Bridging (DCB).

Whether or not you use DCB, you must create QoS policies to classify and tag each network traffic type. You must use Windows PowerShell commands (**New-NetQosPolicy -Name**) to create new QoS policies for each type of traffic on each computer in the cluster. Here are some example commands (make sure to open all PowerShell windows as administrator):

```
New-NetQosPolicy –Name "Live Migration policy" –LiveMigration –MinBandwidthWeightAction
20

New-NetQosPolicy –Name "SMB policy" –SMB –MinBandwidthWeightAction 50

New-NetQosPolicy –Name "Cluster policy" -IPProtocolMatchCondition UDP -
IPDstPortMatchCondition 3343 –MinBandwidthWeightAction 20

New-NetQosPolicy –Name "Management policy" –DestinationAddress 10.7.124.0/24 –
MinBandwidthWeightAction 10
```

These commands use the **MinBandwidthWeightAction** parameter, which specifies a minimum bandwidth as a relative weighting of the total. The **-LiveMigration** and **-SMB** filters are built in Windows Server 2012. They match packets sent to TCP port 6600 (live migration) and TCP port

445 (SMB protocol used for file storage), respectively. The cluster service traffic uses UDP port 3343. The example for management traffic is the address range 10.7.124.0/24, which corresponds to the Hoster subnet in this example.

As a result, live migration, SMB, cluster, and management traffic will have roughly 20 percent, 50 percent, 20 percent, and 10 percent of the total bandwidth, respectively. To display the resulting traffic classes, run the **Get-NetQosTrafficClass** Windows PowerShell command.

If you are not using DCB, Windows will enforce performance isolation through these QoS policies.

If your network adapters and switch support DCB, enable DCB on the network adapters attached to the converged network subnet using Windows PowerShell. The following are examples:

```
Enable-NetAdapterQos "HosterNet1"

Enable-NetAdapterQos "HosterNet2"
```

Note that **HosterNet1** and **HosterNet2** are the names assigned to the individual network adapters and not the NIC Team names.

To verify the settings on a network adapter, use the **get-netadapterqos** command. The following is example output after running the Windows PowerShell command (note that if QoS is not supported on the adapter you will see an error in the output):

```
Network Adapter Name : HosterNet 1

QOS Enabled : True

MACsec Bypass Supported : False

Pre-IEEE DCBX Supported : True

IEEE DCBX Supported : False

Traffic Classes (TCs) : 8

ETS-Capable TCs : 8

PFC-Enabled TCs : 8

Operational TC Mappings : TC TSA Bandwidth Priorities

                  -- --- --------- ----------

                         0  ETS 20%       0-3,5,7

                         1  ETS 50%       4

                         2  ETS 30%       6
```

For an example of a Windows PowerShell script that configures LBFO and performance isolation settings, see ConfigureNetworking.ps1 which can be downloaded at: http://gallery.technet.microsoft.com/scriptcenter/Windows-Server-2012-Cloud-e0b7753a

Step 3: Initial storage configuration

With the initial cluster node configuration complete, you are ready to perform initial storage configuration tasks on all nodes of the cluster. Initial storage configuration tasks include:

- 3.1 Present all shared storage to relevant nodes.

- 3.2 Install and configure MPIO as necessary for multipath scenarios.
- 3.3 Wipe, bring online, and initialize all shared disks.

3.1 Present all shared storage to relevant nodes

In a SAS scenario, connect the SAS adapters to each storage device. Each cluster node should have two adapters in them if high availability to storage access is required.

3.2 Install and configure MPIO as necessary for multipath scenarios

If you have multiple data paths to storage (for example, two SAS cards) make sure to install the Microsoft® Multipath I/O (MPIO) on each node. This step might require you to restart the system. For more information about MPIO, see What's New in Microsoft Multipath I/O.

3.3 Wipe, bring online, and initialize all shared disks

To prevent issues with the storage configuration procedures that are detailed later is this document; confirm that the disks in your storage solution have not been previously provisioned. The disks should have no partitions or volumes. They should also be initialized so that there is a master book record (MBR) or GUID partition table (GPT) on the disks and then brought online. You can use the **Disk Management** console or Windows PowerShell to accomplish this task. This task must be completed on each node in the cluster.

Note

If you have previously configured these disks with Windows Server 2012 Storage Spaces pools, you will need to delete these storage pools prior to proceeding with the storage configuration described in this document. Please refer to the TechNet Wiki Article "How to Delete Storage Pools and Virtual Disks Using PowerShell".

Step 4: File server failover cluster setup

You are now ready to complete the failover cluster settings for the file server cluster. Failover cluster setup includes the following steps:

- 4.1 Run through the Cluster Validation Wizard.
- 4.2 Address any indicated warnings and/or errors.
- 4.3 Complete the Create Failover Cluster Wizard.
- 4.4 Create the clustered storage pool.
- 4.5 Create the quorum virtual disk.
- 4.6 Create the virtual machine storage virtual disk.
- 4.7 Add the virtual machine storage virtual disk to Cluster Shared Volumes.
- 4.8 Add folders to the cluster shared volume.
- 4.9 Configure Quorum Settings.
- 4.10 Add the Scale-Out File Server for Applications role.

4.1 Run through the Cluster Validation Wizard

The Cluster Validation Wizard will query multiple components in the intended cluster hosts and confirm that the hardware and software is ready to support failover clustering. On one of the nodes in the server cluster, perform the following steps to run the Cluster Validation Wizard:

1. In the **Server Manager**, click **Tools**, and then click **Failover Cluster Manager**.
2. In the **Failover Cluster Manager** console, in the **Management** section, click **Validate Configuration**.
3. On the **Before You Begin** page of the **Validate a Configuration Wizard**, click **Next**.
4. On the **Select Servers or a Cluster** page, type the name of the local server, and then click **Add**. After the name appears in the **Selected servers** list, type the name of another Hyper-V cluster member computer, and then click **Add**. Repeat this step for all computers in the Hyper-V cluster. When all of the servers of the Hyper-V cluster appear in the **Selected servers** list, click **Next**.
5. On the **Testing Options** page, click **Next**.
6. On the **Confirmation** page, click **Next**. The time to complete the validation process will vary with the number of nodes in the cluster and can take some time to complete.
7. On the **Summary** page, the summary text will indicate that the configuration is suitable for clustering. Confirm that there is a checkmark in the **Create the cluster now using the validated nodes...** checkbox.

4.2 Address any indicated warnings and/or errors

Click the **Reports** button to see the results of the Cluster Validation. Address any issues that have led to cluster validation failure. After correcting the problems, run the Cluster Validation Wizard again. After the cluster passes validation, then proceed to the next step. Note that you may see errors regarding disk storage. You may see this if you haven't yet initialized the disks. Click **Finish**.

4.3 Complete the Create Failover Cluster Wizard

After passing cluster validation, you are ready to complete the cluster configuration.

Perform the following steps to complete the cluster configuration:

1. On the **Before You Begin** page of the **Create Cluster Wizard**, click **Next**.
2. On the **Access Point for Administering the Cluster** page, enter a valid NetBIOS name for the cluster, and then select the network you want the cluster on and then type in a static IP address for the cluster, and then click **Next**. In this example, the network you would select is the Management Network. Unselect all other networks that appear here.
3. On the **Confirmation** page, clear **Add all eligible storage to the cluster** checkbox and then click **Next**.
4. On the **Creating New Cluster** page you will see a progress bar as the cluster is created.
5. On the **Summary** page, click **Finish**.
6. In the console tree of the **Failover Cluster Manager** snap-in, open the **Networks** node under the cluster name.

7. Right-click the cluster network that corresponds to the management network adapter network ID (subnet), and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is not selected and that **Allow clients to connect through this network** is enabled. In the **Name** text box, enter a friendly name for this network (for example, **ManagmentNet**), and then click **OK**.
8. Right-click the cluster network that corresponds to the Cluster network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is not enabled. In the **Name** text box, enter a friendly name for this network (for example, **ClusterNet**), and then click **OK**.
9. Right-click the cluster network that corresponds to the live migration network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is not enabled. In the **Name** text box, enter a friendly name for this network (for example, **LiveMigrationNet**), and then click **OK**.

4.4 Create a cluster storage pool

Perform the following steps on one of the members of the cluster to create the storage pool:

1. In the left pane of the **Failover Cluster Manager**, expand the server name and then expand the **Storage** node. Click **Storage Pools**.
2. In the **Actions** pane, click **New Storage Pool**.
3. On the **Before You Begin** page, click **Next**.
4. On the **Storage Pool Name** page, enter a name for the storage pool in the **Name** text box. Enter an optional description for the storage pool in the **Description** text box. In the **Select the group of available disks (also known as a primordial pool) that you want to use** list, select the name you assigned to the cluster (this is the NetBIOS name you assigned to the cluster when you created the cluster). Click **Next**.
5. On the **Physical Drives** page, select the drives that you want to participate in the storage pool. Then click **Next**.
6. On the **Confirmation** page, confirm the settings and click **Create**.
7. On the **Results** page, you should receive the message **You have successfully completed the New Storage Pool Wizard**. Remove the checkmark from the **Create a virtual disk when the wizard closes** checkbox. Then click **Close**.

4.5 Create the quorum virtual disk

Now that you have created the storage pool, you can create virtual disks within that storage pool. A virtual disk is sometimes called a logical unit number or LUN and it represents a collection of one or more physical disks from the previously created storage pool. The layout of data across the physical discs can increase the reliability and performance of the physical disk.

You will need to create at least two virtual disks:

- A virtual disk that can be used as a quorum witness disks. This disk can be configured as a 1 GB virtual disk.

- A virtual disk that will be assigned to a cluster shared volume.

Perform the following steps to create the quorum virtual disk:

1. In the **Failover Cluster Manager** console, expand the **Storage** node in the left pane of the console. Right click **Pools** and click **Add Disk**.
2. In the **New Virtual Disk Wizard** on the **Before You Begin** page, click **Next**.
3. On the **Storage Pool** page, select your server name in the **Server** section and then select the storage pool you created earlier in the **Storage pool** section. Click **Next**.
4. On the **Virtual Disk Name** page, enter a name for the virtual disk in the **Name** text box. You can also enter an optional description in the **Description** text box. Click **Next**.
5. On the **Storage Layout** page, in the **Layout** section, select **Mirror**. Click **Next**.
6. On the **Resiliency Settings** select **Two-way mirror** and click **Next**.
7. On the **Size** page, in the **Virtual disk size** text box, enter a size for the new virtual disk, which in this example will be 1 GB. Use the drop down box to select GB. Also, you can put a checkmark in the **Create the largest virtual disk possible, up to the specified size** checkbox, but this is not required or desired when creating a witness disk. When this option is selected it allows the wizard to calculate the largest size virtual disk you can create given the disks you have assigned to the pool, regardless of the number you put in the **Virtual disk size** text box. Click **Next**.
8. On the **Confirmation** page, review your settings and click **Create**.
9. On the **Results** page, put a checkmark in the **Create a volume when this wizard closes** checkbox. Click **Close**.
10. On the **Before You Begin** page of the **New Volume Wizard**, click **Next**.
11. On the **Server and Disk** page, select the name of the cluster from the **Server** list. In the **Disk** section, select the virtual disk you just created. You can identify this disk by looking in the **Virtual Disk** column, where you will see the name of the virtual disk you created. Click **Next**.
12. On the **Size** page, accept the default volume size, and click **Next**.
13. On the **Drive Letter or Folder** page, select the **Drive letter** and select a drive letter. Click **Next**.
14. On the **File System Settings** page, from the **File system** drop down list, select **NTFS**. Use the default setting in the **Allocation unit size** list. Click **Next**.
15. On the **Confirmation** page, click **Create**.
16. On the **Results** page, click **Close**.

4.6 Create the virtual machine storage virtual disk

Perform the following steps to create the **virtual machine storage** virtual disk:

1. In the **Failover Cluster Manager** console, expand the **Storage** node in the left pane of the console. Right click **Pools** and click **Add Disk**.
2. In the **New Virtual Disk Wizard** on the **Before You Begin** page, click **Next**.
3. On the **Storage Pool** page, select your server name in the **Server** section and then select the storage pool you created earlier in the **Storage pool** section. Click **Next**.

4. On the **Virtual Disk Name** page, enter a name for the virtual disk in the **Name** text box. You can also enter an optional description in the **Description** text box. Click **Next**.
5. On the **Storage Layout** page, in the **Layout** section, select **Mirror**. Click **Next**.
6. On the **Resiliency Settings** select **Two-way mirror** and click **Next**.
7. On the **Size** page, in the **Virtual disk size** text box, enter a size for the new virtual disk. Use the drop down box to select MB, GB or TB. Also, you can put a checkmark in the **Create the largest virtual disk possible, up to the specified size** checkbox. When this option is selected it allows the wizard to calculate the largest size virtual disk you can create given the disks you have assigned to the pool, regardless of the number you put in the **Virtual disk size** text box. Click **Next**.
8. On the **Confirmation** page, review your settings and click **Create**.
9. On the **Results** page, put a checkmark in the **Create a volume when this wizard closes** checkbox. Click **Close**.
10. On the **Before You Begin** page of the **New Volume Wizard**, click **Next**.
11. On the **Server and Disk** page, select the name of the cluster from the **Server** list. In the **Disk** section, select the virtual disk you just created. You can identify this disk by looking in the **Virtual Disk** column, where you will see the name of the virtual disk you created. Click **Next**.
12. On the **Size** page, accept the default volume size, and click **Next**.
13. On the **Drive Letter or Folder** page, select the **Don't Assign to a drive letter or folder** and select a drive letter. Click **Next**.
14. On the **File System Settings** page, from **the File system** drop down list, select **NTFS**. Use the default setting in the Allocation unit size list. Note that **ReFS** is not supported in a Cluster Shared Volume configuration. Click **Next**.
15. On the **Confirmation** page, click **Create**.
16. On the **Results** page, click **Close**.

4.7 Add the virtual machine storage virtual disk to Cluster Shared Volumes

The virtual disk you created for virtual machine storage is now ready to be added to a Cluster Shared Volume. Perform the following steps to add the virtual disk to a Cluster Shared Volume.

1. In the **Failover Cluster Manager**, in the left pane of the console, expand the **Storage** node and click **Disks**. In the middle pane of the console, in the **Disks** section, right click the virtual disk you created in the previous step and then click **Add to Cluster Shared Volumes**.
2. Proceed to the next step.

4.8 Add folders to the cluster shared volume

Now you need to create the folders on the virtual disk located on the Cluster Shared Volume to store the virtual machine files and the virtual machine data files.

Perform the following steps to create a file share to store the running VMs of the Hyper-V cluster:

1. Open **Windows Explorer** and navigate to the C: drive and then double-click **Cluster Storage** and then double-click **Volume 1**.

2. Create two folders in **Volume 1**. One of the folders will contain the .vhd files for the virtual machines (for example, VHDdisks) and one folder will contain the virtual machine configuration files (for example, VHDsettings)

4.9 Configure Quorum Settings

Perform the following steps to configure quorum settings for the cluster:

1. In the left pane of the **Failover Cluster Manager** console, right click on the name of the cluster and click **More Actions** and click **Configure Cluster Quorum Settings**.
2. On the **Before You Begin** page, click **Next**.
3. On the **Quorum Configuration Option** page, select **Use typical settings (recommended)** and click **Next**.
4. On the **Confirmation** page, click **Next**.

4.10 Add the Scale-Out File Server for Applications Role

The file server failover cluster will provide continuous availability of the virtual machine files to the nodes in the compute cluster. Windows Server 2012 includes the Scale Out File Server for Applications feature the enables the level of continuous availability required for hosting virtual machine files.

Perform the following steps to configure the file server failover cluster as a Scale-Out File Server for Applications:

1. In the **Failover Cluster Management** console, right click on **Roles** and click **Configure Role**.
2. On the **Before You Begin** page, click **Next**.
3. On the **Select Role** page, select **File Server** and click **Next**.
4. On the **File Server Type** page, select **Scale-Out File Server for application data** and click **Next**.
5. On the **Client Access Point** page, enter a NetBIOS name for the client access point and then click **Next**.
6. On the **Confirmation** page, click **Next**.
7. On the **Summary** page, click **Finish**.

Step 5: Hyper-V Failover Cluster Setup

To setup the Hyper-V compute failover cluster you will need to:

- 5.1 Run through the cluster validation wizard
- 5.2 Address any indicated warnings and/or errors
- 5.3 Complete the Create Cluster Wizard
- 5.4 Verify cluster quorum configuration and modify as necessary
- 5.5 Configure Cluster Networks

5.1 Run through the cluster validation wizard

The Cluster Validation Wizard will query multiple components in the intended cluster hosts and confirm that the hardware and software is ready to support failover clustering. On one of the nodes in the server cluster, perform the following steps on one of the members of the Hyper-V failover cluster to run the Cluster Validation Wizard:

1. In the **Server Manager**, click **Tools**, and then click **Failover Cluster Manager**.
2. In the **Failover Cluster Manager** console, in the **Management** section, click **Validate Configuration**.
3. On the **Before You Begin** page of the **Validate a Configuration Wizard**, click **Next**.
4. On the **Select Servers or a Cluster** page, type the name of the local server, and then click **Add**. After the name appears in the **Selected servers** list, type the name of another Hyper-V cluster member computer, and then click **Add**. Repeat this step for all computers in the Hyper-V cluster. When all of the servers of the Hyper-V cluster appear in the **Selected servers** list, click **Next**.
5. On the **Testing Options** page, click **Next**.
6. On the **Confirmation** page, click **Next**. The time to complete the validation process will vary with the number of nodes in the cluster and can take some time to complete.

On the **Summary** page, the summary text will indicate that the configuration is suitable for clustering. Confirm that there is a checkmark in the **Create the cluster now using the validated nodes...** checkbox.

5.2 Address any indicated warnings and/or errors

Click the **Reports** button to see the results of the Cluster Validation. Address any issues that have led to cluster validation failure. After correcting the problems, run the Cluster Validation Wizard again. After the cluster passes validation, then proceed to the next step. Note that you may see errors regarding disk storage. You may see this if you haven't yet initialized the disks. Click **Finish**.

5.3 Complete the create cluster wizard

After passing cluster validation, you are ready to complete the cluster configuration.

Perform the following steps to complete the cluster configuration:

1. On the **Before You Begin** page of the **Create Cluster Wizard**, click **Next**.
2. On the **Access Point for Administering the Cluster** page, enter a valid NetBIOS name for the cluster, and then select the network you want the cluster on and then type in a static IP address for the cluster, and then click **Next**. The network you will use in this scenario is the infrastructure network.
3. On the **Confirmation** page, clear **Add all eligible storage to the cluster** checkbox and then click **Next**.
4. On the **Creating New Cluster** page you will see a progress bar as the cluster is created.
5. On the **Summary** page, click **Finish**.

5.4 Verify cluster quorum configuration and modify as necessary

In most situations, use the quorum configuration that the cluster software identifies as appropriate for your cluster. Change the quorum configuration only if you have determined that the change is appropriate for your cluster. For more information about quorum configuration see Understanding Quorum Configurations in a Failover Cluster.

In most cases the Hyper-V compute cluster will not have shared storage. Because of this, you may want to set up a file share witness on the file server cluster or another location.

Perform the following steps to configure the quorum model to use the file share witness:

1. In the **Failover Cluster Manager**, in the left pane of the console, right click the cluster name, point to **More Actions** and click **Configure Cluster Quorum Settings**.
2. On the **Before You Begin** page, click **Next**.
3. On the **Select Quorum Configuration Option** page, select **Add** or change the quorum witness. Click **Next**.
4. On the **Select Quorum Witness** page, select **Configure a file share witness (recommended for special configurations)** and click **Next**.
5. On the **Configure File Share Witness** page, enter the path to the file share witness and click **Next**.
6. On the **Confirmation** page, click **Next**.
7. On the **Configure Cluster Quorum Settings** page, click **Next**.
8. On the **Summary** page, click **Finish**.

5.5 Configure Cluster Networks

Perform the following steps to complete the compute cluster by configuring the cluster network settings:

1. In the console tree of the **Failover Cluster Manager** snap-in, open the **Networks** node under the cluster name.
2. Right-click the cluster network that corresponds to the TenantNet network adapter network ID (subnet), and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is *not* selected and that *Do not allow cluster network communication on this network* is enabled. In the **Name** text box, enter a friendly name for this network (for example, TenantNet), and then click **OK**.
3. Right-click the cluster network that corresponds to the infrastructure network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is enabled. In the **Name** text box, enter a friendly name for this network (for example, **HosterNet**), and then click **OK**.

Step 6: Configure Share and Hyper-V settings using a Script

To finalize the Hyper-V configuration, you will need to:

- 6.1 Create Shares and Configure Hyper-V Settings using a Script
- 6.2 Configure Kerberos Constrained Delegation

6.1 Create Shares and Configure Hyper-V Settings using a Script

You will need shares available that will store the virtual machine disk files and the virtual machine configuration files. There are a number of ways that this can be done. In the example used in this document, you will use a script that will:

1. Create shares that will contain the virtual machine disk and configuration files on the CSV in the file server cluster
2. Configure the correct share and NTFS permissions on those folders
3. Configure the servers in the Hyper-V compute cluster to use the correct share locations as default virtual machine disk and configuration file location.

The following script will perform these actions for you.

```
Insert script here (when we get it)
```

6.2 Configure Kerberos Constrained Delegation

In order to fully manage the storage on the file server failover cluster from a machine in the Hyper-V cluster, you will need to configure Kerberos Constrained Delegation. For details on why this is required please see the article, Using Constrained Delegation to remotely manage a server running Hyper-V that uses CIFS/SMB file shares.

Perform the following steps to configure the members of the compute cluster to be trusted for Kerberos Constrained Delegation:

1. On a domain controller responsible for your compute and file server cluster environment, open **Control Panel** and then open **Administrative Tools**. Open **Active Directory Users and Computers**.
2. In the **Active Directory Users and Computers** console, expand the domain name and then click on **Computers**.
3. In the right pane of the console, right click on the name of one of the computers in the Hyper-V compute failover cluster and then click **Properties**.
4. In the **Properties** dialog box for the member of the Hyper-V compute failover cluster member, click on the **Delegation** tab.
5. On the **Delegation** tab, select the **Trust this computer for delegation to the specified services only**. Then select **Use Kerberos only**. Click **Add**.
6. In the **Add Services** dialog box, in the **Service Type** column, find the **cifs** entries. Click on the entry that corresponds to the name of the file server failover cluster and click **OK**.
7. Click **OK** in the server's **Properties** dialog box.

Step 7: Cloud validation

To verify the configuration of your cloud environment, perform the following operations.

- 7.1 Create the TenantNetSwitch.
- 7.2 Create a new virtual machine.
- 7.3 Test network connectivity from the virtual machine.
- 7.4 Perform a live migration.

- 7.5 Perform a quick migration

7.1 Create the TenentNetSwitch

Before you create a virtual machine, you will need to create a virtual switch that is connected to the TenantNet so that the virtual machine can connect to the network. Perform the following steps to create the TenantNet virtual switch:

1. Open the **Hyper-V Manager** console. In the **Hyper-V Manager** console, in the **Actions** pane, click **Virtual Switch Manager**.
2. In the right pane of the **Virtual Switch Manager** dialog box, select **External** and then click **Create Virtual Switch**.
3. In the **Virtual Switch Properties** section of the dialog box, enter a name for the virtual switch in the **Name** text box (in this example it will be **TenantNetSwitch**). In the **Connection type** section, select the **External network** option. Then select the NIC team representing the TenantNet from the drop down box. Click **OK**.

7.2 Create a new virtual machine

To create a new virtual machine in the cluster environment, perform the following steps.

1. Open **Failover Cluster Manager**, click **Roles** under the cluster name, click **Virtual Machines** under the **Actions** pane, and then click **New Virtual Machine**.
2. On the **New Virtual Machine** page, select the cluster node where you want to create the virtual machine, and then click **OK**.
3. On the **Before you Begin** page of the **New Virtual Machine Wizard**, click **Next**.
4. On the **Specify Name and Location** page, enter a friendly name for this virtual machine and then click **Next**.
5. On the **Assign Memory** page, enter the amount of memory that will be used for this virtual machine (minimum for this lab is 1024 MB RAM) and then click **Next**.
6. On the **Configuring Networking** page, click **Next**.
7. On the **Connect Virtual Hard Disk** page, leave the default options selected and click **Next**.
8. On the **Installation Options** page, select **Install an operating system from a boot CD/DVD-ROM** and then select the location where the CD/DVD is located. If you are installing the new operating system based on an ISO file, make sure to select the option Image file (.iso) and browse for the file location. If you prefer to PXE boot, that option will be described in later steps. After you select the appropriate option for your scenario, click **Next**.
9. On the **Completing the New Virtual Machine Wizard** page, review the options, and then click **Finish**.
10. The virtual machine creation process starts. After it is finished, you will see the **Summary** page, where you can access the report created by the wizard. If the virtual machine was created successfully, click **Finish**.
11. If you want to PXE boot the virtual machine, you will need to create a **Legacy Network Adapter**. Right click the new virtual machine and click **Settings**.
12. In the **Settings** dialog box, select the **Legacy Network Adapter** option and click **Add**.

13. In the **Legacy Network Adapter** dialog box, connect it to the virtual switch (such as TenantNetSwitch) and enable virtual LAN identification and assign the appropriate network identifier.

Note that if the virtual machine continues to use the legacy network adapter it will not be able to leverage many of the features available in the Hyper-V virtual switch. You may want to replace the legacy network adapter after the operating system is installed.

At this point your virtual machine is created and you should use the Failover Cluster Manager to start the virtual machine and perform the operating system installation according to the operating system that you choose. For the purpose of this validation, the guest operating system can be any Windows Server version.

7.3 Test network connectivity from the virtual machine

Once you finish installing the operating system in the virtual machine you should log on and verify if this virtual machine was able to obtain IP address from the enterprise network. Assuming that in this network you have a DHCP server, this virtual machine should be able to obtain the IP address. To perform the basic network connectivity test use the following approach.

- Use `ping` command for a reachable IP address in the same subnet.
- Use `ping` command for the same destination but now using the full qualified domain name for the destination host. The goal here is to test basic name resolution.

Note

If you installed Windows 8 Developer Preview in this virtual machine you need to open Windows Firewall with Advanced Security and create a new rule to allow Internet Control Message Protocol (ICMP) before performing the previous tests. This may be true for other hosts you want to ping − confirm that the host-based firewall on the target allows for ICMP Echo Requests.

After you confirm that this basic test is working properly, leave a command prompt window open and enter the command ping <Destination_IP_Address_or_FQDN> -t. The goal here is to have a continuous test while you perform the live migration to the second node.

Note

If you prefer to work with PowerShell, instead of the ping command you can use the Test-Connection command. This cmdlet provides you a number of connectivity testing options that exceed what is available with the simple ping command.

7.4 Perform a live migration

To perform a live migration of this virtual machine from the current cluster node to the other node in the cluster, perform the following steps.

1. In the **Failover Cluster Manager**, click **Roles** under the cluster name. On the **Roles** pane, right click the virtual machine that you created, click **Move**, click **Live Migration**, and then click **Select Node**.

2. On the **Move Virtual Machine** page, select the node that you want to move the virtual machine to and click **OK**.

You will notice in the **Status** column when the live migration starts, it will take some time for the **Information** column to update the current state of the migration. While the migration is taking place you can go back to the virtual machine that has the ping running and observe if there is any packet loss.

7.5 Perform a quick migration

To perform the quick migration of this virtual machine from the current node to the other one, perform the following steps.

1. On the **Failover Cluster Manager**, click **Roles** under the cluster name. In the **Roles** pane, right-click the virtual machine that you created, click **Move**, click **Quick Migration** and then click **Select Node**.
2. On the **Move Virtual Machine** window, select the node that you want to move the virtual machine to, and then click **OK**.

You will notice in the status that the quick migration will start faster than the live migration did. While the migration is taking place you can go back to the virtual machine that has the ping running and observe if there is any packet loss.

Building Your Cloud Infrastructure: Converged Data Center without Dedicated Storage Nodes

This document contains the instructions that you need to follow to create a private or public cloud configuration that uses:

- A converged network infrastructure for live migration, cluster, storage, management, and tenant traffic
- All network traffic moves through the Hyper-V virtual switch
- Hyper-V Virtual Switch Quality of Service (QoS)
- Hyper-V Virtual Switch port ACLs and 802.1q VLAN tagging
- NIC Teaming for network bandwidth aggregation and failover
- Well-connected storage using SAS JBOD enclosures

The design pattern discussed in this document is one of three design patterns we suggest for building the core cloud network, compute and storage infrastructure. For information about the other two cloud infrastructure design patterns, please see:

- Building Your Cloud Infrastructure: Non-Converged Data Center Configuration
- Building Your Cloud Infrastructure: Converged Data Center with File Server Storage

Design Considerations and Requirements for the Converged Data Center without Dedicated Storage Node Pattern

The Converged Data Center without Dedicated Storage Nodes cloud infrastructure design patterns focuses on the following key requirements in the areas of networking, compute and storage:

Networking

- You prefer that network traffic to and from both the host operating system and the guest operating systems running on the host move through a single network adapter team. This requirement is met by using Windows Server 2012 NIC Teaming (LBFO) and passing all traffic through the Hyper-V virtual switch.
- You require that live migration, cluster, storage, management and tenant traffic all receive guaranteed levels of bandwidth. The requirement is met by using Hyper-V virtual switch QoS policies.
- You require that infrastructure traffic (which includes Live Migration, cluster, storage and management traffic) and tenant traffic be isolated from each other. This requirement is met by using Hyper-V virtual switch port ACLs and 802.1q VLAN tagging.

Storage

- You prefer to scale your cloud infrastructure by adding scale units consisting of compute and storage capacity together. This requirement is met by connecting the Hyper-V servers directly to SAS storage, without having dedicated file servers.
- You require cost-effective storage. This requirement is met by using SAS disks in shared JBOD enclosures managed through Storage Spaces.
- You require a resilient storage solution. This requirement is met by having multiple Hyper-V servers configured as a failover cluster, and having a well-connected (shared JBODs) storage so that all members of the failover cluster are directly connected to storage, and by having Storage Spaces configured in as a mirrored space to guarantee against data loss in the case of disk failures
- You require that each member of the Hyper-V failover cluster be able to access the shared storage where the VHDs are located. This requirement is met by using Windows Server 2012 Failover Clustering and Cluster Shared Volumes Version 2 (CSV v2) volumes to store virtual machine files and metadata.

Compute

- You require that the virtual machines will be continuously available and resilient to hardware failures. This requirement can be met by using Windows Server 2012 Failover Clustering together with the Hyper-V Server Role.

- You require the highest number of virtual machines possible per host server (i.e. increased density). This requirement is met by using processor offload technologies, such as Remote Direct Memory Access (RDMA), Receive Side Scaling, Receive Side Coalescing (RSC), and Datacenter Bridging (DCB). Please note that in the default configuration presented here (without a dedicated storage access NIC), RDMA and DCB cannot be used because these technologies require direct access to the hardware and must bypass much of the virtual networking stack. This is similar to the situation with Single Root I/O Virtualization (SR-IOV). For optimal performance, especially in the context of network access to storage, a separate NIC team would be required to support these hardware offload acceleration technologies.

Overview

A Windows Server® 2012 cloud infrastructure is a high-performing and highly available Hyper-V cluster that hosts virtual machines that can be managed to create private or public clouds using the Converged Data Center without Dedicated Storage Nodes infrastructure design pattern. This document explains how to configure the basic building blocks for such a cloud. It does not cover the System Center or other management software aspects of deployments; the focus is on configuring the core Windows Server hosts that are used to build cloud infrastructure.

For background information on creating clouds using Windows Server 2012, see Building Infrastructure as a Service Clouds using Windows Server "8".

This cloud configuration consists of the following:

- Multiple computers in a Hyper-V failover cluster.

  A Hyper-V cluster is created using the Windows Server 2012 Failover Cluster feature. The Windows Server 2012 Failover Clustering feature set is tightly integrated with the Hyper-V server role and enables a high level of availability from a compute and networking perspective. In addition, Windows Server 2012 Failover Clustering enhances virtual machine mobility which is critical in a cloud environment. For example, Live Migration is enhanced when performed in a failover cluster deployment because the cluster can automatically evaluate which node in the cluster is optimal for migrated virtual machine placement.
- A converged networking infrastructure that supports multiple cloud traffic profiles.

  Each computer in the Hyper-V failover cluster should have at least two network adapters that will be used for the converged network. This converged network will host all traffic to and from the server, which includes both host system traffic and guest/tenant traffic. The network adapters will be teamed by using Windows Server 2012 Load Balancing and Failover (LBFO) NIC Teaming. The NICs can be either two or more 10 GbE or 1 GbE network adapters. These NICs will be used for live migration, cluster, storage, management (together referred to as "infrastructure" traffic) and tenant traffic.
- The appropriate networking hardware to connect all of the computers in the Hyper-V cluster to each other and to a larger network from which the hosted virtual machines are available.

The following figure provides a high-level view of the scenario architecture. The teamed network adapters on each member of the failover cluster are connected to what will be referred to as a converged subnet in this document. We use the term converged subnet to make it clear that all traffic to and from the Hyper-V cluster members and the tenant virtual machines on each cluster

member must flow through the teamed converged subnet network adapter. Both the host operating system and the tenants connect to the network through the Hyper-V virtual switch. The figure also shows an optional network adapter that is RDMA-capable that can be used for storage traffic, such as when storage is being hosted on a share on a remote file server. This document does not discuss this optional configuration option. For more information about this storage option, please see the document on the Converged Data Center with File Server Storage design pattern at http://technet.microsoft.com/en-us/library/hh831738.

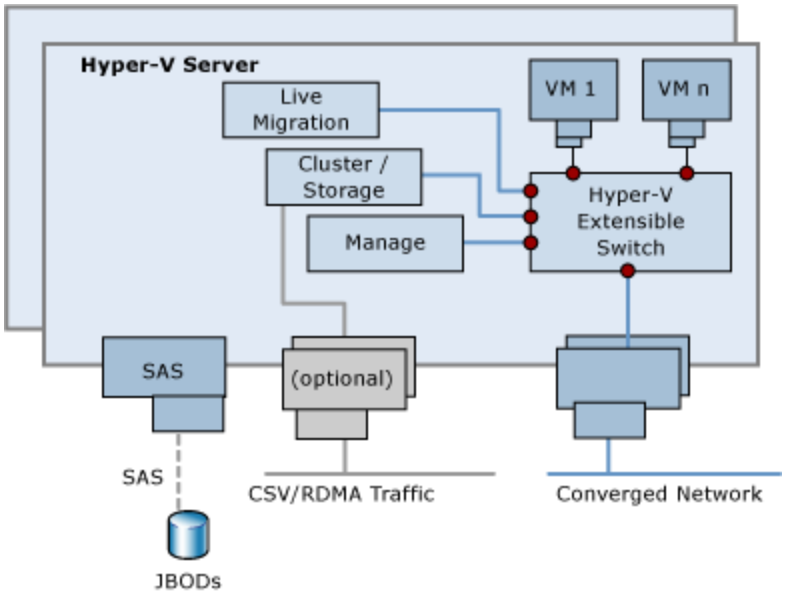


Figure 1 High level overview of cluster member networking configuration

Note

At least one Active Directory Domain Services (AD DS) domain controller is needed for centralized security and management of the cluster member computers (not shown). It must be reachable by all of the cluster member computers, including the members of the shared storage cluster. DNS services are also required and are not depicted.

Figure 2 provides an overview of traffic flows on each member of the Hyper-V cluster. The figure calls out the following significant issues in the configuration:

- Each cluster node member uses a virtual network adapter to connect to the Hyper-V Extensible Switch, which connects it to the physical network.
- Each tenant virtual machine is also connected to the Hyper-V Extensible Switch using a virtual network adapter.
- Network adapters named **ConvergedNet1** and **ConvergedNet2** participate in a teamed physical network adapter configuration using the Windows Server 2012 Failover and Load Balancing feature.
- Windows Server 2012 Hyper-V virtual switch QoS is used to assure that each traffic type (such as live migration, cluster, management and tenant) has a predictable amount of bandwidth available.

- Traffic isolation is enabled by 802.1q VLAN tagging so that host traffic is not visible to the tenants.
- Windows Server 2012 Hyper-V virtual switch port ACLs can also be used for more granular access control at the network level.

It is important to note that Remote Direct Memory Access (RDMA) cannot be used on the converged network because it does not work together with the Hyper-V virtual switch. This will be an issue if you prefer to use high performance SMB 3 connectivity to file server based storage for virtual machine disk and configuration files. In the file server storage scenario, you can introduce addition RDMA capable adapters to connect to storage.

Note

Virtual local area networks (VLANs) are not assigned to each tenant because VLAN-based network isolation is not a scalable solution and is not compatible with Windows Server 2012 network virtualization. VLANs are used to isolate infrastructure traffic from tenant traffic in this scenario.

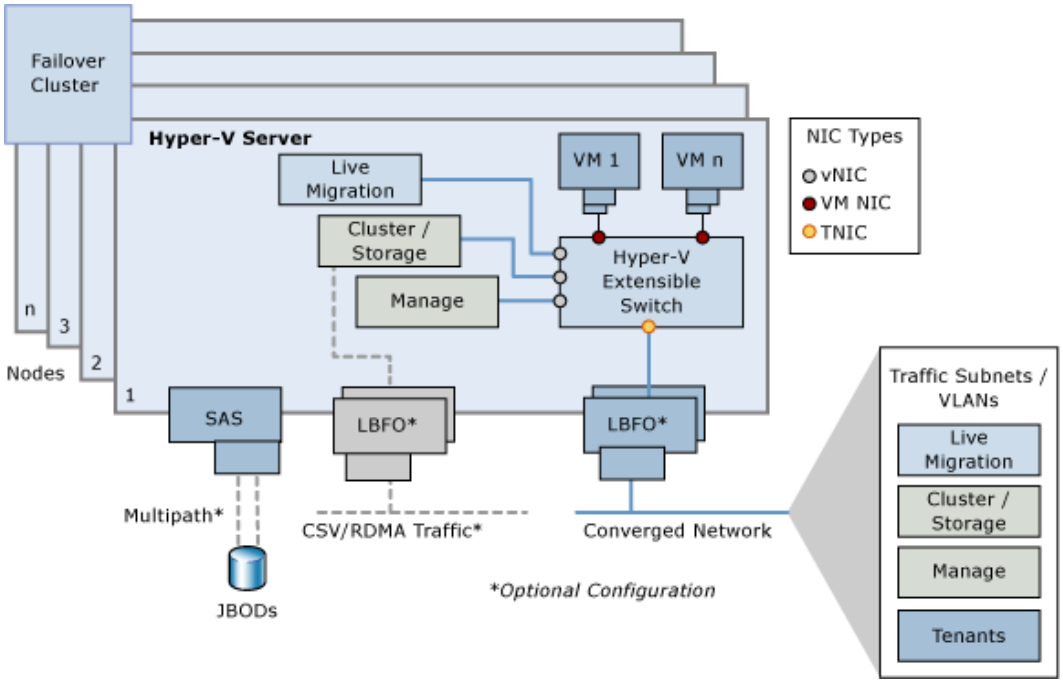

Figure 2 Overview of cluster member traffic flows

This configuration highlights the following technologies and features of Windows Server 2012:

- **Load Balancing and Failover (LBFO)**: Load Balancing and Failover logically combines multiple network adapters to provide bandwidth aggregation and traffic failover to prevent connectivity loss in the event of a network component failure. Load Balancing with Failover is also known as NIC Teaming in Windows Server 2012.
- **Hyper-V Virtual Switch Quality of Service (QoS)**: In Windows Server 2012, QoS includes new bandwidth management features that let you provide predictable network performance to virtual machines on a server running Hyper-V.

- **Hyper-V Virtual Switch Quality of Service (QoS)**: In Windows Server 2012 the Hyper-V virtual switch includes new capabilities that enhance the security of the cloud infrastructure. You can now use Port Access Control Lists (Port ACLs) and VLAN support to get network isolation similar to what you find when using physical network isolation.
- **Storage Spaces**: Storage Spaces makes it possible for you to create cost-effective disk pools that present themselves as a single mass storage location on which virtual disks or volumes can created and formatted.

Note

Although this configuration uses local SAS storage to meet the cost-effective storage requirement, you can easily choose to use other types of storage, such as SAN storage. You can find more information about storage configuration for a non-SAS scenario in the document Building Your Cloud Infrastructure: Non-Converged Enterprise Configuration, which describes how to configure the SAN storage.

The following sections describe how to set up this cloud configuration using UI-based tools and Windows PowerShell.

After the cloud is built, you can validate the configuration by doing the following:

- Install and configure virtual machines
- Migrate running virtual machines between servers in the Hyper-V cluster (live migration)

Install and configure the Converged Data Center without Dedicated Storage Server cloud infrastructure

In this section, we will cover the step by step of how to configure the cloud infrastructure scale unit described in this document.

Creating this cloud infrastructure configuration consists of the following steps:

- Step 1: Initial node configuration
- Step 2: Initial network configuration
- Step 3: Initial storage configuration
- Step 4: Failover cluster setup
- Step 5: Configure Hyper-V settings
- Step 6: Cloud validation

The following table summarizes the steps that this document describes:

Step	Task	Target	Tasks
1	Initial Node Configuration	All Nodes	• 1.1-Add appropriate VLANs to interface ports on the physical switch for each traffic type:

			• Management (untagged, default) • Tenants (tagged) • Live migration (tagged) • Cluster/cluster shared volumes (CSV) (tagged) • 1.2-Enable BIOS settings required for Hyper-V • 1.3-Perform a clean operating system installation • 1.4-Perform post installation tasks: • Set Windows PowerShell execution policy • Enable Windows PowerShell remoting • Enable Remote Desktop Protocol and Firewall rule • Join the domain • 1.5-Install roles and features using default settings, rebooting as needed • Hyper-V (plus management tools) • Storage Services • Failover clustering (plus management tools) • File Sharing and storage management tools
2	Initial Network Configuration	All Nodes	• 2.1-Disable unused and disconnected interfaces and rename active connections • 2.2-Create the converged network adapter team (rename as necessary) and

			assign IP addresses or configure DHCP as appropriate.
			• 2.3-Create the Hyper-V vSwitch and Management virtual network adapter (PowerShell)
			• 2.4-Rename Management virtual network adapter (optional)
			• 2.5-Create additional virtual network adapters and assign VLAN IDs (PowerShell)
			  • Live migration
			  • Cluster
			• 2.6-Rename the virtual network adapters
			• 2.7-Assign static IPs as necessary
			• 2.8-Configure QoS for different traffic types and configure the default minimum bandwidth for the switch

3	Initial Storage Configuration	Single Node	• 3.1-Present all shared storage to relevant nodes • 3.2-For multipath scenarios, install and configure multipath I/O (MPIO) as necessary • 3.3-All shared disks: Wipe, bring online and initialize
4	Failover Cluster Setup	Single Node	• 4.1-Run through the Cluster Validation Wizard • 4.2-Address any indicated warnings and/or errors • 4.3-Complete the Create Cluster Wizard (setting name and IP but do not add eligible storage) • 4.4-Create the clustered

			storage pool. • 4.5-Create the quorum virtual disk • 4.6-Create the virtual machine storage virtual disk. • 4.7-Add the virtual machine storage virtual disk to cluster shared volumes. • 4.8-Add folders to the cluster shared volume. • 4.9-Configure quorum settings • 4.10-Configure cluster networks to prioritize traffic.
5	Hyper-V Configuration	All Nodes	• 5.1-Change default file locations, mapping to CSV volumes
6	Cloud Validation	Single Node	• 6.1-Create a virtual machine, attaching an existing operating system VHD and tagging to the appropriate VLAN • 6.2-Test network connectivity from the virtual machine. • 6.3-Perform a Live Migration • 6.4-Perform a quick migration

Step 1: Initial node configuration

In step 1, you will perform the following steps on all nodes of the Hyper-V cluster:

- 1.1 Add appropriate VLANS to the interface ports on the physical switch.
- 1.2 Enable BIOS settings required for Hyper-V.
- 1.3 Perform a clean operating system installation.
- 1.4 Perform post-installation tasks.
- 1.5 Install roles and features using the default settings.

1.1 Add appropriate VLANS to the interface ports on the physical switch

Cluster nodes will be configured to use different VLAN tags for the following traffic types:

- **Management traffic** – untagged/default
- **Tenant traffic** – tagged
- **Live migration traffic** – tagged
- **Cluster and CSV traffic** – tagged

VLANs are configured to enable traffic isolation and quality of service policies. Define the VLAN tag numbers for each traffic type and then configure your switch with the appropriate VLAN port numbers. The procedures for doing this will vary with the switch make and model. Please refer to your switch documentation for more information. Note that management traffic is typically not tagged because it can interfere with a number of core host system activities. While you can tag the management traffic, you may run into problem with issues such as PXE boot. Therefore, we recommend that you do not tag the management traffic.

1.2 Enable BIOS settings required for Hyper-V

You will need to enable virtualization support in the BIOS of each cluster member prior to installing the Hyper-V server role. The procedure for enabling processor virtualization support will vary with your processors' make and model and the system BIOS. Please refer to your hardware documentation for the appropriate procedures.

1.3 Perform a clean operating system installation

Install Windows Server 2012 using the Full Installation option.

1.4 Perform post-installation tasks

There are several tasks you need to complete on each node after the operating system installation is complete. These include:

- Join each node to the domain
- Enable remote access to each node via the Remote Desktop Protocol.
- Set the Windows PowerShell execution policy.
- Enable Windows PowerShell remoting.

Perform the following steps to join each node to the domain:

1. Press the **Windows Key** on the keyboard and then press **R**. Type **Control Panel** and then click **OK**.
2. In the **Control Panel** window, click **System and Security**, and then click **System**.
3. In the **System** window under **Computer name, domain, and workgroup settings**, click **Change settings**.
4. In the **System Properties** dialog box, click **Change**.
5. Under **Member of**, click **Domain**, type the name of the domain, and then click **OK**.

Run the following Windows PowerShell commands on each node to enable remote access using the Remote Desktop Protocol, to enable PowerShell execution policy and enable PowerShell Remoting:

```
(Get-WmiObject Win32_TerminalServiceSetting -Namespace
root\cimv2\terminalservices).SetAllowTsConnections(1,1)

Set-ExecutionPolicy Unrestricted –Force

Enable-PSRemoting –Force
```

1.5 Install roles and features using the default settings

The following roles and features will be installed on each node of the cluster:

- Hyper-V and Hyper-V management Tools
- Failover cluster and failover cluster management tools
- Storage management tools

Perform the following steps on each node in the cluster to install the required roles and features:

1. In **Server Manager**, click **Dashboard** in the console tree.
2. In **Welcome to Server Manager**, click **2 Add roles and features**, and then click **Next**.
3. On the **Before You Begin** page of the **Add Roles and Features Wizard**, click **Next**.
4. On the **Installation Type** page, click **Next**.
5. On the **Server Selection** page, click **Next**.
6. On the **Server Roles** page, select **Hyper-V** from the **Roles** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Click **Next**.
7. On the **Features** page, select **Failover Clustering** from the **Features** list. In the **Add Roles and Features Wizard** dialog box, click **Add Features**. Expand **Remote Server Administrator Tools** and then expand **Role Administration Tools**. Expand **File Services Tools**. Select **Share and Storage Management Tool**. Click **Next**.

   Note
   If you plan to use Multipath I/O for your storage solution, select the Multipath I/O feature while performing step 7.
8. On the **Hyper-V** page, click **Next**.
9. On the **Virtual Switches** page, click **Next**.
10. On the **Migration** page, click **Next**.
11. On the **Default Stores** page, click **Next**.
12. On the **Confirmation** page, put a checkmark in the **Restart the destination server automatically if required** checkbox and then in the **Add Roles and Features** dialog box click **Yes**, then click **Install**.
13. On the **Installation progress** page, click **Close** after the installation has succeeded.
14. Restart the computer. This process might require restarting the computer twice. If so, the installer will trigger the multiple restarts automatically.

After you restart the server, open **Server Manager** and confirm that the installation completed successfully. Click Close on the Installation Progress page.

Step 2: Initial network configuration

The network configuration on each node in the cluster needs to be configured to support the converged networking scenario where all traffic, including infrastructure and tenant traffic, moves through the Hyper-V virtual switch. You will perform the following procedures on each of the nodes in the cluster to complete the initial network configuration:

- 2.1 Disable unused and disconnected interfaces and rename active connections.
- 2.2 Create a converged network adapter team and configure IP addressing information.
- 2.3 Create the Hyper-V virtual switch and management virtual network adapter.
- 2.4 Rename the management virtual network adapter (optional).
- 2.5 Create additional virtual network adapters and assign VLAN IDs.
- 2.6 Rename virtual network adapters (optional).
- 2.7 Assign static IP addresses to the virtual network adapters.
- 2.8 Configure QoS for different traffic types and configure the default minimum bandwidth for the virtual switch.

2.1 Disable unused and disconnected interfaces and rename active connections

You can simplify the configuration and avoid errors when running the wizards and running PowerShell commands by disabling all network interfaces that are either unused or disconnected. You can disable these network interfaces in the **Network Connections** window.

For the remaining network adapters, do the following:

1. Connect them to the converged network switch ports.
2. To help you more easily recognize the active network adapters, rename them with names that indicate their use or their connection to the intranet or Internet (for example, **ConvergedNet1** and **ConvergedNet2**). You can do this in the **Network Connections** window.

2.2 Create a converged network adapter team

Network Load Balancing and Failover (LBFO) enables bandwidth aggregation and network adapter failover to prevent connectivity loss in the event of a network card or port failure. This feature is often referred to as "NIC Teaming". In this scenario you will create one team that will be connected to the ConvergedNet subnet.

To configure the network adapter teams by using **Server Manager**, do the following on *each computer in the cluster*:

Note

Several steps in the following procedure will temporarily interrupt network connectivity. We recommend that all servers be accessible over a keyboard, video, and mouse (KVM) switch so that you can check on the status of these machines if network connectivity is unavailable for more than five minutes.

1. From **Server Manager**, click **Local Server** in the console tree.
2. In **Properties**, click **Disabled**, which you'll find next to **Network adapter teaming**.
3. In the **NIC Teaming** window, click the name of the server computer in **Servers**.
4. In **Teams**, click **Tasks**, and then click **New Team**.
5. In the **New Team** window, in the **Team Name** text box, enter the name of the network adapter team for the converged traffic subnet (example: **ConvergedNet Team**).
6. In the **Member adapters** list select the two network adapters connected to the converged traffic subnet (in this example, **ConvergedNet1** and **ConvergedNet2**), and then click **OK**. Note that there may be a delay of several minutes before connectivity is restored after making this change. To ensure that you see the latest state of the configuration, right click your server name in the **Servers** section in the **NIC Teaming** window and click **Refresh Now**. There may be a delay before the connection displays as **Active**. You may need to refresh several times before seeing the status change.
7. Close the **NIC Teaming** window.

Configure a static IPv4 addressing configuration for the new network adapter team connected to the converged traffic subnet (example: **ConvergedNet Team**). This IP address is the one that you will use when connecting to the host system for management purposes. You can do this in the **Properties** of the team in the **Network Connections** window. You will see a new adapter where the name of the teamed network adapter is the name you assigned in step 5. You will lose connectivity for a few moments after assigning the new IP addressing information.

Note

You might need to manually refresh the display of the NIC Teaming window to show the new team and there may be a delay in connectivity as the network adapter team is created. If you are managing this server remotely, you might temporarily lose connectivity to the server.

2.3 Create the Hyper-V virtual switch and management virtual network adapter

In this scenario, all traffic will flow through the Hyper-V virtual switch. This includes the host operating system traffic (cluster/CSV, management and live migration) and guest/tenant traffic. You will create the virtual switch in Windows PowerShell instead of using the Hyper-V console. The reason for this is that when you create the virtual switch in the Hyper-V console, you are unable to specify the Minimum Bandwidth Mode, which defaults to Absolute (requiring a bits per second value) as opposed to Weighted mode (configurable via Windows PowerShell) which allows for a relative range from 1 to 100. For more information on the New-VMSwitch cmdlet, please see New-VMSwitch.

Run the following Windows PowerShell command on each member of the cluster to create the Hyper-V virtual switch and the management traffic virtual network adapter:

```
New-VMSwitch "ConvergedNetSwitch" -MinimumBandwidthMode weight -NetAdapterName
"ConvergedNetTeam" -AllowManagementOS 1
```

Please note that during this step you created both the Hyper-V virtual switch and the management virtual NIC.

Note that if you are performing this action of an RDP connection, the connection may drop for a few moments.

2.4 Rename the management virtual network adapter (optional)

The management virtual network adapter that was created when you created the virtual switch now appears in the **Network Connections** window and it was assigned a generic name such as **vEthernet** (**ConvergedNetSwitch**). You should rename this virtual network adapter to make it easier to identify in subsequent operations. Right-click the new virtual network adapter and click **Rename** and assign the virtual network adapter a new name (for example, Management).

2.5 Create additional virtual network adapters and assign VLAN IDs

The Hyper-V virtual switch now has a single virtual network adapter that will be used for hosting operating system management traffic. You now will create two additional virtual network adapters: one for live migration traffic and one for cluster traffic.

Run the following Windows PowerShell commands to create the live migration traffic virtual network adapter, the cluster traffic virtual network adapter, assign the live migration virtual network adapter a VLAN ID and assign the cluster virtual network adapter a VLAN ID:

```
Add-VMNetworkAdapter -ManagementOS -Name "LiveMigration" -SwitchName "ConvergedNetSwitch"

Add-VMNetworkAdapter -ManagementOS -Name "Cluster" -SwitchName "ConvergedNetSwitch"

Set-VMNetworkAdapterVlan -ManagementOS -VMNetworkAdapterName LiveMigration -Access -
VlanId 2160

Set-VMNetworkAdapterVlan -ManagementOS -VMNetworkAdapterName Cluster -Access -VlanId 2161
```

In the preceding example, the **–VMNetworkAdapterName** represents the name of the virtual network adapter.

2.6 Rename virtual network adapters (optional)

The live migration and cluster virtual network adapters you created in the previous step now appear in the **Network Connections** window and they were assigned default names, such as **vEthernet (Cluster)**. You should rename these virtual network adapters to make them easier to identify in subsequent operations. Right-click each of these virtual network adapters, click **Rename** and assign the virtual network adapter a new name (for example, live migration and cluster)

2.7 Assign static IP addresses to the virtual network adapters

You now need to assign IP addresses to your virtual network adapters. This can be done through DHCP or you can assign static addresses. Make sure that each of the virtual network adapters is assigned an IP address on a different network ID – this will become important later when you configure your cluster networking configuration. You can use the Networking Control Panel applet or Windows PowerShell to assign IP addressing information to the virtual network adapters. For example:

```
Set-NetIPInterface -InterfaceAlias "LiveMigration" -dhcp Disabled; new-NetIPAddress -
PrefixLength 8 -InterfaceAlias "LiveMigration" -IPv4Address 11.0.0.x
```

2.8 Configure QoS for different traffic types and configure the default minimum bandwidth for the switch

In this step you will configure QoS weightings that define the minimal share of bandwidth assigned to each of the virtual network adapters. You can determine the percentage of bandwidth that can be allocated to a particular virtual network adapter by adding all the weight values together and then dividing the individual weight assigned to a virtual network adapter by the total.

Perform the following steps to add weight values to the cluster, management and live migration virtual network adapters:

Run the following Windows PowerShell commands to assign a weight value to the cluster virtual network adapter, assign a weight value to the management virtual network adapter, assign a weight value to the live migration virtual network adapter and assign a default weight value for any future virtual network adapters you create:

```
Set-VMNetworkAdapter -ManagementOS -Name "Cluster" -MinimumBandwidthWeight 40

Set-VMNetworkAdapter -ManagementOS -Name ConvergedNetSwitch -MinimumBandwidthWeight 5

Set-VMNetworkAdapter -ManagementOS -Name "LiveMigration" -MinimumBandwidthWeight 20

Set-VMSwitch "ConvergedNetSwitch" -DefaultFlowMinimumBandwidthWeight 10
```

Note

VMNetworkAdapter name is listed under 'Device Name' in the **Network Connections** user interface.

Step 3: Initial storage configuration

With the initial cluster node configuration complete, you are ready to perform initial storage configuration tasks on all nodes of the cluster. Initial storage configuration tasks include:

- 3.1 Present all shared storage to relevant nodes.
- 3.2 Install and configure MPIO as necessary for multipath scenarios.
- 3.3 Wipe, bring online, and initialize all shared disks.

3.1 Present all shared storage to relevant nodes

In a SAS scenario, connect the SAS adapters to each storage device. Each cluster node should have two adapters in them if high availability to storage access is required.

3.2 Install and configure MPIO as necessary for multipath scenarios

If you have multiple data paths to storage (for example, two SAS cards) make sure to install the Microsoft® Multipath I/O (MPIO) on each node. This step might require you to restart the system. For more information about MPIO, see What's New in Microsoft Multipath I/O.

3.3 Wipe, bring online, and initialize all shared disks

To prevent issues with the storage configuration procedures that are detailed later is this document; confirm that the disks in your storage solution have not been previously provisioned. The disks should have no partitions or volumes. They should also be initialized so that there is a master book record (MBR) or GUID partition table (GPT) on the disks, and then brought online. You can use the **Disk Management** console or Windows PowerShell to accomplish this task. This task must be completed on each node in the cluster.

To discover disks that can participate in a pool you can use the PowerShell command Get-PhysicalDisk | ? BusType -Eq "SAS". All disks in the **CanPool** column that read TRUE are eligible for pooling.

Note

If you have previously configured these disks with Windows Server 2012 Storage Spaces pools, you will need to delete these storage pools prior to proceeding with the storage configuration described in this document. Please refer to the TechNet Wiki Article, How to Delete Storage Pools and Virtual Disks Using PowerShell.

Step 4: Failover cluster setup

You are now ready to complete the failover cluster settings. Failover cluster setup includes the following steps:

- 4.1 Run through the Cluster Validation Wizard.
- 4.2 Address any indicated warnings and/or errors.
- 4.3 Complete the Create Failover Cluster Wizard.
- 4.4 Create the clustered storage pool.
- 4.5 Create the quorum virtual disk.
- 4.6 Create the virtual machine storage virtual disk.
- 4.7 Add the virtual machine storage virtual disk to Cluster Shared Volumes.
- 4.8 Add folders to the cluster shared volume.
- 4.9 Configure Quorum Settings.
- 4.10 Configure cluster networks to prioritize traffic.

4.1 Run through the Cluster Validation Wizard

The Cluster Validation Wizard will query multiple components in the intended cluster hosts and confirm that the hardware and software is ready to support failover clustering. On one of the nodes in the server cluster, perform the following steps to run the Cluster Validation Wizard:

1. In the **Server Manager**, click **Tools**, and then click **Failover Cluster Manager**.
2. In the **Failover Cluster Manager** console, in the **Management** section, click **Validate Configuration**.
3. On the **Before You Begin** page of the **Validate a Configuration Wizard**, click **Next**.
4. On the **Select Servers or a Cluster** page, type the name of the local server, and then click **Add**. After the name appears in the **Selected servers** list, type the name of another Hyper-V cluster member computer, and then click **Add**. Repeat this step for all computers in the Hyper-V cluster. When all of the servers of the Hyper-V cluster appear in the **Selected servers** list, click **Next**.
5. On the **Testing Options** page, click **Next**.
6. On the **Confirmation** page, click **Next**. The time to complete the validation process will vary with the number of nodes in the cluster and can take some time to complete.
7. On the **Summary** page, the summary text will indicate that the configuration is suitable for clustering. Confirm that there is a checkmark in the **Create the cluster now using the validated nodes...** checkbox.

4.2 Address any indicated warnings and/or errors

Click the **Reports** button to see the results of the Cluster Validation. Address any issues that have led to cluster validation failure. After correcting the problems, run the Cluster Validation Wizard again. After the cluster passes validation, then proceed to the next step. Note that you may see errors regarding disk storage. You may see this if you haven't yet initialized the disks. Click **Finish**.

4.3 Complete the Create Failover Cluster Wizard

After passing cluster validation, you are ready to complete the cluster configuration.

Perform the following steps to complete the cluster configuration:

1. On the **Before You Begin** page of the **Create Cluster Wizard**, click **Next**.
2. On the **Access Point for Administering the Cluster** page, enter a valid NetBIOS name for the cluster, and then select the network you want the cluster on and then type in a static IP address for the cluster, and then click **Next**. In this example, the network you would select is the Management Network. Unselect all other networks that appear here.
3. On the **Confirmation** page, clear **Add all eligible storage to the cluster** checkbox and then click **Next**.
4. On the **Creating New Cluster** page you will see a progress bar as the cluster is created.
5. On the **Summary** page, click **Finish**.
6. In the console tree of the **Failover Cluster Manager** snap-in, open the **Networks** node under the cluster name.

7. Right-click the cluster network that corresponds to the management network adapter network ID (subnet), and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is enabled. In the **Name** text box, enter a friendly name for this network (for example, **ManagmentNet**), and then click **OK**.
8. Right-click the cluster network that corresponds to the Cluster network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network is selected** and that **Allow clients to connect through this network** is *not* enabled. In the **Name** text box, enter a friendly name for this network (for example, **ClusterNet**), and then click **OK**.
9. Right-click the cluster network that corresponds to the live migration network adapter network ID (subnet) and then click **Properties**. On the **General** tab, confirm that **Allow cluster communications on this network** is selected and that **Allow clients to connect through this network** is *not* enabled. In the **Name** text box, enter a friendly name for this network (for example, **LiveMigrationNet**), and then click **OK**.

4.4 Create a clustered storage pool

Perform the following steps on one of the members of the cluster to create the storage pool:

1. In the left pane of the **Failover Cluster Manager**, expand the server name and then expand the **Storage** node. Click **Storage Pools**.
2. In the **Actions** pane, click **New Storage Pool**.
3. On the **Before You Begin** page, click **Next**.
4. On the **Storage Pool Name** page, enter a name for the storage pool in the **Name** text box. Enter an optional description for the storage pool in the Description text box. In the **Select the group of available disks (also known as a primordial pool) that you want to use** list, select the name you assigned to the cluster (this is the NetBIOS name you assigned to the cluster when you created the cluster). Click **Next**.
5. On the **Physical Drives** page, select the drives that you want to participate in the storage pool. Then click **Next**.
6. On the **Confirmation** page, confirm the settings and click **Create**.
7. On the **Results** page, you should receive the message **You have successfully completed the New Storage Pool Wizard**. Remove the checkmark from the **Create a virtual disk when the wizard closes** checkbox. Then click **Close**.

4.5 Create the quorum virtual disk

Now that you have created the storage pool, you can create virtual disks within that storage pool. A virtual disk is sometimes called a logical unit number or LUN and it represents a collection of one or more physical disks from the previously created storage pool. The layout of data across the physical discs can increase the reliability and performance of the physical disk.

You will need to create at least two virtual disks:

- A virtual disk that can be used as a quorum witness disks. This disk can be configured as a 1 GB virtual disk.

- A virtual disk that will be assigned to a cluster shared volume.

Perform the following steps to create the **quorum** virtual disk:

1. In the **Failover Cluster Manager** console, expand the **Storage** node in the left pane of the console. Right click **Pools** and click **Add Disk**.
2. In the **New Virtual Disk Wizard** on the **Before You Begin** Page, click **Next**.
3. On the **Storage Pool** page, select your server name in the **Server** section and then select the storage pool you created earlier in the **Storage pool** section. Click **Next**.
4. On the **Virtual Disk Name** page, enter a name for the virtual disk in the **Name** text box. You can also enter an optional description in the **Description** text box. Click **Next**.
5. On the **Storage Layout** page, in the **Layout** section, select **Mirror**. Click **Next**.
6. On the **Resiliency Settings** select **Two-way mirror** and click **Next**.
7. On the **Size** page, in the **Virtual disk size** text box, enter a size for the new virtual disk, which in this example will be 1 GB. Use the drop down box to select GB. Also, you can put a checkmark in the **Create the largest virtual disk possible, up to the specified size** checkbox, but this is not required or desired when creating a witness disk. When this option is selected, it allows the wizard to calculate the largest size virtual disk you can create given the disks you have assigned to the pool, regardless of the number you put in the **Virtual disk size** text box. Click **Next**.
8. On the **Confirmation** page, review your settings and click **Create**.
9. On the **Results** page, put a checkmark in the **Create a volume when this wizard closes** checkbox. Click **Close**.
10. On the **Before You Begin** page of the **New Volume Wizard**, click **Next**.
11. On the **Server and Disk** page, select the name of the cluster from the **Server** list. In the **Disk** section, select the virtual disk you just created. You can identify this disk by looking in the **Virtual Disk** column, where you will see the name of the virtual disk you created. Click **Next**.
12. On the **Size** page, accept the default volume size, and click **Next**.
13. On the **Drive Letter or Folder** page, select **Drive letter** and select a drive letter. Click **Next**.
14. On the **File System Settings** page, from the **File system** drop down list, select **NTFS**. Use the default setting in the **Allocation unit size** list. Click **Next**.
15. On the **Confirmation** page, click **Create**.
16. On the **Results** page, click **Close**.

4.6 Create the virtual machine storage virtual disk

Perform the following steps to create the **virtual machine storage** virtual disk:

1. In the **Failover Cluster Manager** console, expand the **Storage** node in the left pane of the console. Right click **Pools** and click **Add Disk**.
2. In the **New Virtual Disk Wizard** on the **Before You Begin** page, click **Next**.
3. On the **Storage Pool** page, select your server name in the **Server** section and then select the storage pool you created earlier in the **Storage pool** section. Click **Next**.
4. On the **Virtual Disk Name** page, enter a name for the virtual disk in the **Name** text box. You can also enter an optional description in the **Description** text box. Click **Next**.

5. On the **Storage Layout** page, in the **Layout** section, select **Mirror**. Click **Next**.
6. On the **Resiliency Settings** select **Two-way mirror** and click **Next**.
7. On the **Size** page, in the **Virtual disk size** text box, enter a size for the new virtual disk. Use the drop down box to select MB, GB or TB. Also, you can put a checkmark in the **Create the largest virtual disk possible, up to the specified size** checkbox. When this option is selected, it allows the wizard to calculate the largest size virtual disk you can create given the disks you have assigned to the pool, regardless of the number you put in the **Virtual disk size** text box. Click Next.
8. On the **Confirmation** page, review your settings and click **Create**.
9. On the **Results** page, put a checkmark in the **Create a volume when this wizard closes** checkbox. Click **Close**.
10. On the **Before You Begin** page of the **New Volume Wizard**, click **Next**.
11. On the **Server and Disk** page, select the name of the cluster from the **Server** list. In the **Disk** section, select the virtual disk you just created. You can identify this disk by looking in the **Virtual Disk** column, where you will see the name of the virtual disk you created. Click **Next**.
12. On the **Size** page, accept the default volume size, and click **Next**.
13. On the **Drive Letter or Folder** page, select the **Don't Assign to a drive letter or folder** and select a drive letter. Click **Next**.
14. On the **File System Settings** page, from the **File system** drop down list, select **NTFS**. Use the default setting in the **Allocation unit size** list. Note that **ReFS** is not supported in a **Cluster Shared Volume** configuration. Click **Next**.
15. On the **Confirmation** page, click **Create**.
16. On the **Results** page, click **Close**.

4.7 Add the virtual machine storage virtual disk to Cluster Shared Volumes

The virtual disk you created for virtual machine storage is now ready to be added to a Cluster Shared Volume. Perform the following steps to add the virtual disk to a Cluster Shared Volume.

1. In the **Failover Cluster Manager**, in the left pane of the console, expand the **Storage** node and click **Disks**. In the middle pane of the console, in the **Disks** section, right click the virtual disk you created in the previous step and then click **Add to Cluster Shared Volumes**.
2. Proceed to the next step.

4.8 Add folders to the cluster shared volume

Now you need to create the folders on the virtual disk located on the Cluster Shared Volume to store the virtual machine files and the virtual machine data files.

Perform the following steps to create a file share to store the running VMs of the Hyper-V cluster:

1. Open **Windows Explorer** and navigate to the C: drive and then double-click **Cluster Storage** and then double-click **Volume 1**.
2. Create two folders in **Volume 1**. One of the folders will contain the .vhd files for the virtual machines (for example, VHDdisks) and one folder will contain the virtual machine configuration files (for example, VHDsettings)

4.9 Configure Quorum Settings

Perform the following steps to configure quorum settings for the cluster:

1. In the left pane of the **Failover Cluster Manager** console, right click on the name of the cluster and click **More Actions** and click **Configure Cluster Quorum Settings**.
2. On the **Before You Begin** page, click **Next**.
3. On the **Quorum Configuration Option** page, select **Use typical settings (recommended)** and click **Next**.
4. On the **Confirmation** page, click **Next**.

4.10 Configure cluster networks to prioritize traffic

The cluster will use the network with the lowest metric for CSV traffic and the second lowest metric for live migration. Windows PowerShell® is the only method available to prescriptively specify the CSV network. You can set the live migration network via the Hyper-V management console, which you will do in Step 5: Configure Hyper-V settings.

Run the following Windows PowerShell commands on one node of the failover cluster to set the metric for the cluster network traffic, set the metric for the live migration network traffic and set the metric for the management network traffic:

```
(Get-ClusterNetwork "ClusterNet" ).Metric = 100

(Get-ClusterNetwork "LiveMigrationNet" ).Metric = 500

(Get-ClusterNetwork "ManagementNet" ).Metric = 1000
```

Step 5: Configure Hyper-V settings

To finalize the Hyper-V configuration, you will need to take the following step:

- 5.1 Change default file locations for virtual machine files.

5.1 Change default file locations for virtual machine files

On each Hyper-V cluster member, perform the following steps on to change the default file locations for virtual machine files:

1. In **Server Manager**, click **Tools**, then click **Hyper-V Manager**.
2. From the console tree of the **Hyper-V Manager**, right-click the name of the Hyper-V server, and then click **Hyper-V Settings**.
3. In the **Hyper-V Settings** dialog box, click **Virtual Hard Disks** under **Server**, type the file share location in **Specify the default folder to store virtual hard disk files**, and then click **Apply**. For example, `c:\clusterstorage\volume1\VHDdisks`.
4. Click **Virtual Machines** under **Server**, type the file folder location in **Specify the default folder to store virtual machine configuration files**, and then click **OK** For example, `c:\clusterstorage\volume1\VHDsettings`.

Step 6: Cloud validation

To verify the configuration of your cloud environment, perform the following operations.

- 6.1 Create a new virtual machine.
- 6.2 Test network connectivity from the virtual machine.
- 6.3 Perform a live migration.
- 6.4 Perform a quick migration.

6.1 Create a new virtual machine

To create a new virtual machine in the cluster environment, perform the following steps.

1. Open **Failover Cluster Manager**, click **Roles** under the cluster name, click **Virtual Machines** under the **Actions** pane, and then click **New Virtual Machine**.
2. On the **New Virtual Machine** page, select the cluster node where you want to create the virtual machine, and then click **OK**.
3. On the **Before you Begin** page of the **New Virtual Machine Wizard**, click **Next**.
4. On the **Specify Name and Location** page, enter a friendly name for this virtual machine and then click **Next**.
5. On **the Assign Memory** page, enter the amount of memory that will be used for this virtual machine (minimum for this lab is 1024 MB RAM) and then click **Next**.
6. On the **Configuring Networking** page, click **Next**.
7. On the **Connect Virtual Hard Disk** page, leave the default options selected and click **Next**.
8. On the **Installation Options** page, select **Install an operating system from a boot CD/DVD-ROM** and then select the location where the CD/DVD is located. If you are installing the new operating system based on an ISO file, make sure to select the option **Image file** (.iso) and browse for the file location. If you prefer to PXE boot, that option will be described in later steps. After you select the appropriate option for your scenario, click **Next**.
9. On the **Completing the New Virtual Machine Wizard** page, review the options, and then click **Finish**.
10. The virtual machine creation process starts. After it is finished, you will see the **Summary** page, where you can access the report created by the wizard. If the virtual machine was created successfully, click **Finish**.
11. If you want to PXE boot the virtual machine, you will need to create a **Legacy Network Adapter**. Right click the new virtual machine and click settings.
12. In the **Settings** dialog box, select the **Legacy Network Adapter** option and click **Add**.
13. In the **Legacy Network Adapter** dialog box, connect it to the virtual switch (such as ConvergedNetSwitch) and enable virtual LAN identification and assign the appropriate network identifier.

Note

If the virtual machine continues to use the legacy network adapter it will not be able to leverage many of the features available in the Hyper-V virtual switch. You may want to replace the legacy network adapter after the operating system is installed.

At this point your virtual machine is created and you should use the Failover Cluster Manager to start the virtual machine and perform the operating system installation according to the operating system that you choose. For the purpose of this validation, the guest operating system can be any Windows Server version.

6.2 Test network connectivity from the virtual machine

Once you finish installing the operating system in the virtual machine you should log on and verify if this virtual machine was able to obtain IP address from the enterprise network. Assuming that in this network you have a DHCP server, this virtual machine should be able to obtain the IP address. To perform the basic network connectivity test use the following approach.

- Use `ping` command for a reachable IP address in the same subnet.
- Use `ping` command for the same destination but now using the full qualified domain name for the destination host. The goal here is to test basic name resolution.

Note

If you installed Windows "8" Developer Preview in this virtual machine you need to open Windows Firewall with Advanced Security and create a new rule to allow Internet Control Message Protocol (ICMP) before performing the previous tests. This may be true for other hosts you want to ping − confirm that the host-based firewall on the target allows for ICMP Echo Requests.

After you confirm that this basic test is working properly, leave a command prompt window open and enter the command, `ping <Destination_IP_Address_or_FQDN> -t`. The goal here is to have a continuous test while you perform the live migration to the second node.

Note

If you prefer to work with PowerShell, instead of the ping command you can use the Test-Connection command. This cmdlet provides you a number of connectivity testing options that exceed what is available with the simple ping command.

6.3 Perform a live migration

To perform a live migration of this virtual machine from the current cluster node to the other node in the cluster, perform the following steps.

1. In the **Failover Cluster Manager**, click **Roles** under the cluster name. On the **Roles** pane, right click the virtual machine that you created, click **Move**, click **Live Migration**, and then click **Select Node**.
2. On the **Move Virtual Machine** page, select the node that you want to move the virtual machine to and click **OK**.

You will notice in the **Status** column when the live migration starts, it will take some time for the **Information** column to update the current state of the migration. While the migration is taking place you can go back to the virtual machine that has the ping running and observe if there is any packet loss.

6.4 Perform a quick migration

To perform the quick migration of this virtual machine from the current node to the other one, perform the following steps.

1. On the **Failover Cluster Manager**, click **Roles** under the cluster name. In the **Roles** pane, right-click the virtual machine that you created, click **Move**, click **Quick Migration** and then click **Select Node**.
2. On the **Move Virtual Machine** window, select the node that you want to move the virtual machine to, and then click **OK**.

You will notice in the status that the quick migration will start faster than the live migration did. While the migration is taking place you can go back to the virtual machine that has the ping running and observe if there is any packet loss.

Dynamic Access Control: Scenario Overview

In Windows Server 2012, you can apply data governance across your file servers to control who can access information and to audit who has accessed information. Dynamic Access Control lets you:

- Identify data by using automatic and manual classification of files. For example, you could tag data in file servers across the organization.
- Control access to files by applying safety-net policies that use central access policies. For example, you could define who can access health information within the organization.
- Audit access to files by using central audit policies for compliance reporting and forensic analysis. For example, you could identify who accessed highly sensitive information.
- Apply Rights Management Services (RMS) protection by using automatic RMS encryption for sensitive Microsoft Office documents. For example, you could configure RMS to encrypt all documents that contain Health Insurance Portability and Accountability Act (HIPAA) information.

The Dynamic Access Control feature set is based on infrastructure investments that can be used further by partners and line-of-business applications, and the features can provide great value for organizations that use Active Directory. This infrastructure includes:

- A new authorization and audit engine for Windows that can process conditional expressions and central policies.
- Kerberos authentication support for user claims and device claims.
- Improvements to the File Classification Infrastructure (FCI).
- RMS extensibility support so partners can provide solutions that encrypt non-Microsoft files.

In this scenario

The following scenarios and guidance are included as part of this content set:

Dynamic Access Control Content Roadmap

Scenario	Evaluate	Plan	Deploy	Operate
Scenario: Central Access Policy Creating Central access policies for files allow organizations to centrally deploy and manage authorization policies that include conditional expressions using user claims, device claims, and resource properties. These polices are based on compliance and business regulatory requirements. These policies are created and hosted in Active Directory, therefore making it easier to manage and deploy. **Deploying Claims Across Forests** In Windows Server 2012, the AD DS maintains a 'claims dictionary' in each forest and all claim types in use within the forest are defined at the Active Directory forest level. There	Dynamic Access Control: Scenario Overview Deploy Claims Across Forests	Plan for a Central Access Policy Deployment • Process to map a business request to a central access policy • Delegating of administration for Dynamic Access Control • Exception Mechanisms for Planning Central Access Policies Best Practices for Using User Claims • Choosing the right configuration to enable claims in your user domain • Operations to enable user claims • Considerations for using user claims in the file server discretionary ACLs without using Central Access Policies Using Device Claims and Device Security Groups	Deploy a Central Access Policy (Demonstration Steps) Deploy Claims Across Forests (Demonstration Steps)	• Modeling a central access policy

Scenario	Evaluate	Plan	Deploy	Operate
are many scenarios where a principal may need to traverse a trust boundary. This scenario describes how a claim traverses a trust boundary.		• Considerations for using static device claims • Operations to enable device claims Tools for Deployment • Data Classification Toolkit		
Scenario: File Access Auditing Security auditing is one of the most powerful tools to help maintain the security of an enterprise. One of the key goals of security audits is regulatory compliance. For example, industry standards such as Sarbanes Oxley, HIPAA, and Payment Card Industry (PCI) require enterprises to follow a strict set of rules related to data security and privacy. Security audits help establish the presence or absence of such policies; thereby, they prove compliance or	Scenario: File Access Auditing	Plan for File Access Auditing	Deploy Security Auditing with Central Audit Policies (Demonstration Steps)	• Monitor the Central Access Policies that Apply on a File Server • Monitor the Central Access Policies Associated with Files and Folders • Monitor the Resource Attributes on Files and Folders • Monitor Claim Types • Monitor User and Device Claims During

noncompliance with these standards. Additionally, security audits help detect anomalous behavior, identify and mitigate gaps in security policy, and deter irresponsible behavior by creating a record of user activity that can be used for forensic analysis.				Sign-in • Monitor Central Access Policy and Rule Definitions • Monitor Resource Attribute Definitions • Monitor the Use of Removable Storage Devices.
Scenario: Access-Denied Assistance Today, when users try to access a remote file on the file server, the only indication that they would get is that access is denied. This generates requests to helpdesk or IT administrators that need to figure out what the issue is and often the administrators have a hard time getting the appropriate context from users which makes it harder to resolve the issue. In Windows Server 2012, the goal is to	Scenario: Access-Denied Assistance	Plan for Access-Denied Assistance • Determine the access-denied assistance model • Determine who should handle access requests • Customize the access-denied assistance message • Plan for exceptions • Determine how access-denied assistance is deployed	Deploy Access-Denied Assistance (Demonstration Steps)	

Scenario	Evaluate	Plan	Deploy	Operate
try and help the information worker and business owner of the data to deal with the access denied issue before IT gets involved and when IT gets involved, provide all the right information for a quick resolution. One of the challenges in achieving this goal is that there is no central way to deal with access denied and every application deals with it differently and thus in Windows Server 2012, one of the goals is to improve the access-denied experience for Windows Explorer.				
Scenario: Classification-Based Encryption for Office Documents Protection of sensitive information is mainly about mitigating risk for the organization. Various compliance regulations, such as HIPAA or Payment	Scenario: Classification-Based Encryption for Office Documents	Planning Considerations for Encryption of Office Documents	Deploy Encryption of Office Files (Demonstration Steps)	

Scenario	Evaluate	Plan	Deploy	Operate
Card Industry Data Security Standard (PCI-DSS), dictate encryption of information, and there are numerous business reasons to encrypt sensitive business information. However, encrypting information is expensive, and it might impair business productivity. Thus, organizations tend to have different approaches and priorities for encrypting their information. To support this scenario, Windows Server 2012 provides the ability to automatically encrypt sensitive Windows Office files based on their classification. This is done through file management tasks that invoke Active Directory Rights Management Server (AD RMS) protection for sensitive documents a few seconds after the

file is identified as being a sensitive file on the file server.				
Scenario: Get Insight into Your Data by Using Classification Reliance on data and storage resources has continued to grow in importance for most organizations. IT administrators face the growing challenge of overseeing larger and more complex storage infrastructures while simultaneously being tasked with the responsibility to ensure total cost of ownership is maintained at reasonable levels. Managing storage resources is not just about the volume or availability of data anymore, but also about the enforcement of company policies and knowing how storage is consumed to enable efficient utilization and	Scenario: Get Insight into Your Data by Using Classification	Plan for Automatic File Classification	Deploy Automatic File Classification (Demonstration Steps)	

Scenario	Evaluate	Plan	Deploy	Operate
compliance to mitigate risk. File Classification Infrastructure provides insight into your data by automating classification processes so that you can manage your data more effectively. The following classification methods are available with File Classification Infrastructure: manual, programmatically, and automatic. This scenario focuses on the automatic file classification method.				
Scenario: Implement Retention of Information on File Servers A retention period is the amount of time that a document should be kept before it is expired. Depending on the organization, the retention period can be different. You can classify files in a folder as having a	Scenario: Implement Retention of Information on File Servers	Plan for Retention of Information on File Servers	Deploy Implementing Retention of Information on File Servers (Demonstration Steps)	

Scenario	Evaluate	Plan	Deploy	Operate
short, medium, or long-term retention period and then assign the timeframe for each period. You may want to keep a file indefinitely by putting it on legal hold. File Classification Infrastructure and File Server Resource Manager uses file management tasks and file classification to apply retention periods for a set of files. You can assign a retention period on a folder and then use a file management task to configure how long an assigned retention period is to last. When the files in the folder are about to expire, the owner of the file gets a notification email. You can also classify a file as being on legal hold so that the file management task will not expire the file.				

Note
Dynamic Access Control is not supported on ReFS (Resilient File System).

Scenario: Central Access Policy

Central access policies for files enable organizations to centrally deploy and manage authorization policies that include conditional expressions that use user groups, user claims, device claims, and resource properties. (Claims are assertions about the attributes of the object with which they are associated). For example, to access high-business-impact (HBI) data, a user must be a full-time employee, obtain access from a managed device, and log on with a smart card. These policies are defined and hosted in Active Directory Domain Services (AD DS).

Organizational access policies are driven by compliance and business regulatory requirements. For example, if an organization has a business requirement to restrict access to personally identifiable information (PII) in files to only the file owner and members of the human resources (HR) department who are allowed to view PII information, this policy applies to PII files wherever they are located on file servers across the organization. In this example, you need to be able to:

- Identify and mark the files that contain PII.
- Identify the group of HR members who are allowed to view PII information.
- Create a central access policy that applies to all files that contain PII wherever they are located on file servers across the organization.

The initiative to deploy and enforce an authorization policy can come for many reasons and apply to multiple levels of the organization. The following are some example policy types:

- **Organization-wide authorization policy.** Most commonly initiated from the information security office, this authorization policy is driven by compliance or a high-level organization requirements, and it is relevant across the organization. For example, HBI files are accessible to only full-time employees.
- **Departmental authorization policy.** Each department in an organization has some special data-handling requirements that they want to enforce. For example, the finance department might want to limit access to finance servers to the finance employees.
- **Specific data-management policy.** This policy usually relates to compliance and business requirements, and it is targeted at protecting the correct access to the information that is being managed. For example, financial institutions might implement information walls so that analysts do not access brokerage information and brokers do not access analysis information.
- **Need-to-know policy.** This authorization policy type is typically used in conjunction with the previous policy types. For example, vendors should be able to access and edit only files that pertain to a project they are working on.

Real-life environments also teach us that every authorization policy needs to have exceptions so that organizations can quickly react when important business needs arise. For example, executives who cannot find their smart cards and need quick access to HBI information can call the Help Desk to get a temporary exception to access that information.

Central access policies act as security umbrellas that an organization applies across its servers. These policies enhance (but do not replace) the local access policies or discretionary access control lists (DACL) that are applied to files and folders. For example, if a DACL on a file allows access to a specific user, but a central policy that is applied to the file restricts access to the same user, the user cannot obtain access to the file. If the central access policy allows access, but the DACL does not allow access, the user cannot obtain access to the file.

A central access policy rule has the following logical parts:

- **Applicability.** A condition that defines which data the policy applies to, such as Resource.BusinessImpact=High.
- **Access conditions.** A list of one or more access control entries (ACEs) that define who can access the data, such as Allow | Full Control | User.EmployeeType=FTE.
- **Exceptions.** An additional list of one or more ACEs that define an exception for the policy, such as MemberOf(HBIExceptionGroup).

The following two figures show the workflow in central access and audit policies.

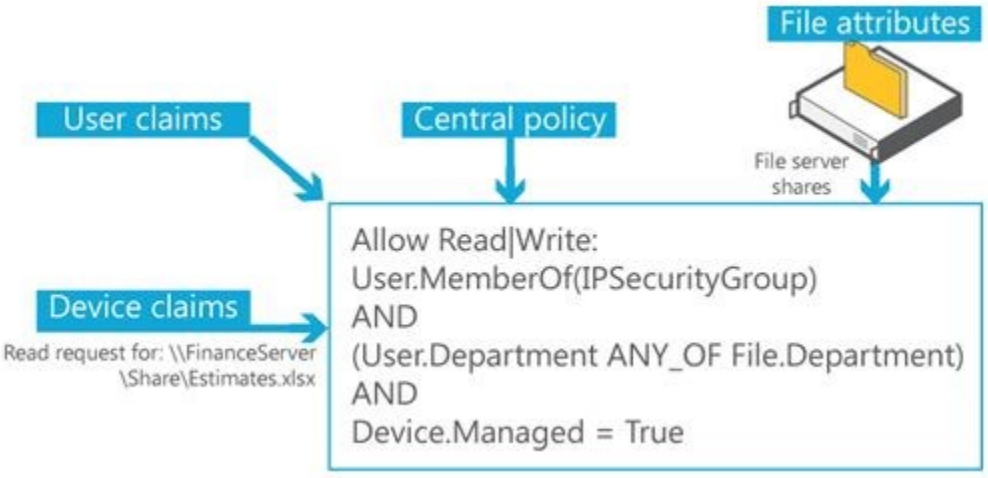

Figure 1 Central access and audit policy concepts

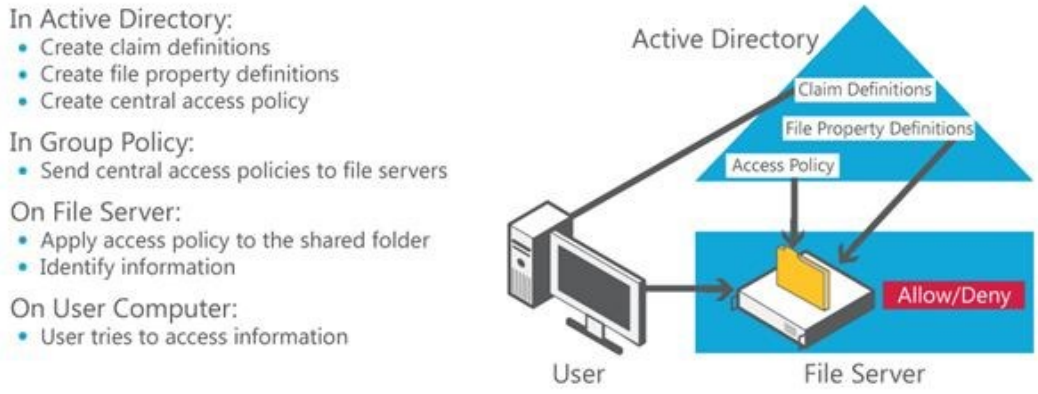

Figure 2 Central access policy workflow

The central authorization policy combines the following components:

- A list of centrally defined access rules that target specific types of information, such as HBI or PII.
- A centrally defined policy that contains a list of rules.
- A policy identifier that is assigned to each file on the file servers to point to a specific central access policy that should be applied during the access authorization.

The following figure demonstrates how you can combine policies into policy lists to centrally control access to files.

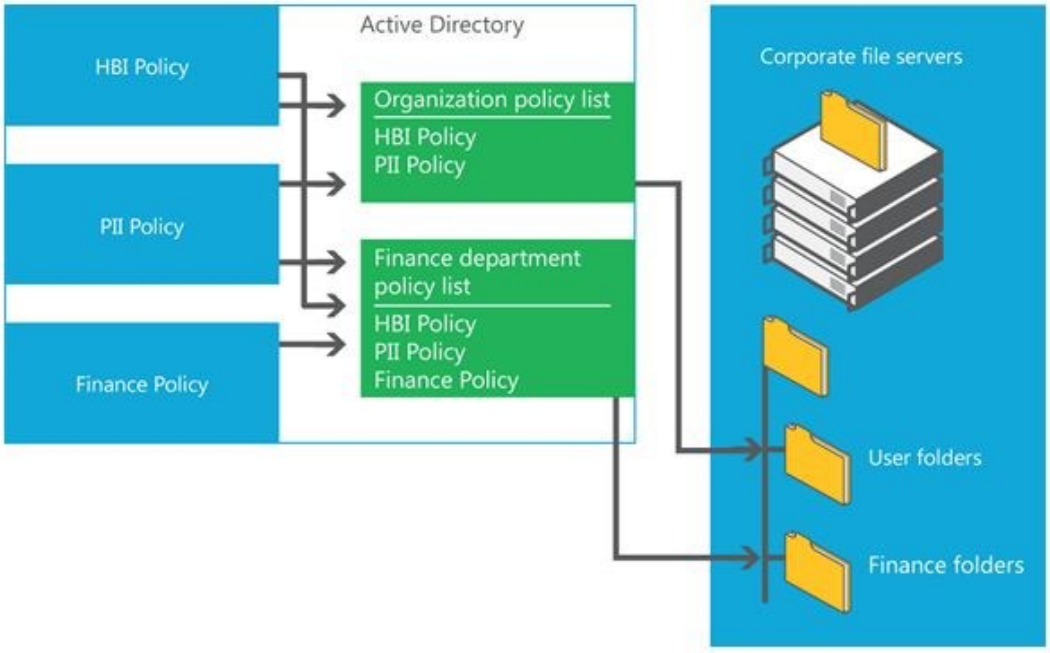

Figure 3 Combining policies

In this scenario

The following guidance is available to you for central access policies:

- Plan for a Central Access Policy Deployment
- Deploy a Central Access Policy (Demonstration Steps)
- Dynamic Access Control: Scenario Overview

Roles and features included in this scenario

The following table lists the roles and features that are part of this scenario and describes how they support it.

Role/feature	How it supports this scenario
Active Directory Domain Services role	AD DS in Windows Server 2012 introduces a claims-based authorization platform that enables the creation of user claims and device claims, compound identity, (user plus device claims), new central access policy (CAP) models, and the use of file-classification information in authorization decisions.

Role/feature	How it supports this scenario
File and Storage Services Server role	File and Storage Services provides technologies that help you set up and manage one or more file servers that provide central locations on your network where you can store files and share them with users. If your network users need access to the same files and applications, or if centralized backup and file management are important to your organization, you should set up one or more computers as a file server by adding the File and Storage Services role and the appropriate role services to the computers.
Windows client computer	Users can access files and folders on the network through the client computer.

Plan for a Central Access Policy Deployment

The need to control the information in enterprise-level organizations for compliance and business regulations is one of the drivers in the consolidation trend where large amounts of information from users' desktops and departmental file shares are moved into centrally managed file servers. The initiative to deploy and enforce an authorization policy may come for different reasons and from multiple levels of the organization:

- **Organization-wide authorization policy**: most commonly initiated from the Information Security office, this authorization policy is driven from compliance or very high level organization requirement and would be relevant across the organization. For example: High Business Impact files should be accessible by full time employees only
- **Departmental authorization policy**: each department in an organization has some special data handling requirements that they would like to enforce. This is very common in distributed organization. For example: the finance department might want to limit all access to finance servers to the finance employees
- **Specific data management policy**: this policy usually relates to compliance and business requirements and is targeted at protecting the right access to information that is being managed. For example: Preventing modification or deletion of files that are under retention or files that are under eDiscovery
- **Need to know policy**: This is a catch all authorization policy type and most probably used in conjunction with the policy types mentioned above. Examples include: Vendors should be able to access and edit only files that pertain to a project that they are working on.
  In financial institutions, information walls are important so that analysts do not access brokerage information and brokers do not access analysis information

Process to map a business request to a central access policy

1. Understand and translate business intent
2. Express access policy in Windows Server 2012 constructs
3. Determine the user groups, resource properties and claim types
4. Determine the servers where this policy should be applied to

Understand and translate business intent

Business determines that a central access policy is needed. The next step is to decide on the content (resources) that you want to apply policies. Then create a list of all the policies you want to apply to your content. For example some of the common policies that apply to the finance department of an organization would be:

- Archived finance documents should only be read by members of the Finance department.
- Members of the Finance department should only be able to access documents in their own country.
- Only Finance Administrators should have write access. An exception will be allowed for members of the FinanceException group. This group will have read access.

Express access policy in Windows Server 2012 constructs

The next step in the planning process is to translate the policies you require into expressions. A central access policy is targeted at providing an easy interpretation from a business requirement language to an authorization language.
A central policy in Windows Server 2012has the following distinct parts:

- Applicability: A condition that defines which data the policy applies to
  (Example: Resource.BusinessImpact=High)
- Access conditions: A list of one or more Access Control Entries (ACE) that defines who can access the data
  (Example: Allow | Full Control | User.EmployeeType=FTE)
- Exception: An additional list of one or more access control entries that define an exception for the policy
  (Example: MemberOf(HBIExceptionGroup)

Determine the user groups, resource properties and claim types

In this step, the expressions that were created for the policies are broken down and analyzed to figure out what resource properties, security groups as well as potential user claims need to be created to deploy the specific policies. Note that before using user claims, you should review the relevant section on user claims in this topic. Remember that you can always use security groups in case that you do not have the appropriate user claim attribute available in your environment.

Determine the servers where this policy should be applied to

The next step is to determine what file servers you want to deploy the access policies you have decided on. For example you can have a finance access policy that you want to roll out only to the finance file servers.

Planning Guidelines for Deploying Central Access Policies

There are multiple ways to deploy central access policies, based on different configurations in your environment. You can choose to have a simple deployment with security groups or have more advanced central access policies using user claims and device claims. The following sections in this topic discuss the different deployment options available to you base on the configuration you choose. The design and deployment guidance for each of these is discussed in further detail:

- Using Security Groups for Dynamic Access Control
- Using User Claims
- Using Device Claims and Device Security Groups

For a list of all configuration options and guidance on which configuration to choose, see the section, Configuring central access policies with different options

For a high-level view of the different deployment options, requirements and configurations, see the Appendix: Deployment Configurations for Central Access Policies

Using Security Groups for Dynamic Access Control

You don't have to use user claims in order to implement Dynamic Access Control in your organization. In fact, you can use security groups with very minimal upgrade requirements to your current environment. You can use security groups in conjunction with central access policies and conditional expressions in Windows Server 2012. This way you can use Dynamic Access Control to limit access to specific data using the existing security group mechanism.

To use Dynamic Access Control with security groups you need the following in your environment:

- A Windows Server 2012 File Server
- A domain with a Windows Server 2012 schema (so that you can define central access policies)

Using security groups to limit access to data

Dynamic Access Control can help you limit access to data to the specific groups of people. The steps to achieve this are:

1. Tagging the data by marking the folders that contain confidential data

2. Configuring a Central Access Rule that specifies that only specific security groups can access data that are tagged in a specific way
3. Applying a Central Access Policy to the appropriate Windows Server 2012 File Servers in your organization

For a detailed walkthrough of using security groups, see the Dynamic Access Control Blog.

Using conditional expressions to reduce complexity of security groups

You can use Dynamic Access Control to considerably reduce the complexity of a combinatorial number of security groups (for example, from 2,000 to less than a 100) so that you can have a clear understanding of who can access what data and you are able to easily adjust access when people move between different roles in the company.

In a typical enterprise environment there are a large number of users, departments, security groups, and thus, a large number of access control lists (ACLs). Also, if a person moves from one department to the other, that involves updating a large number of security groups. This results in a lot of IT overhead and Dynamic Access Control can help with reducing the workload of IT admins for managing security group. The steps required for this are:

1. Tag all the folders with the appropriate values, for example, department, country, and sensitive.
2. Decide on the combinations of expressions to be used in in Windows ACL. For example, you would use **MemberOf (Spain_Security_Group) AND MemberOf (Finance_Security_Group) AND MemberOf(Sensitive_Security_Group)** to limit access to Spain's finance department sensitive information.
3. Create specific central access rules with these expressions that target certain security groups and specific folders on the files servers.

For a detailed walkthrough of using Dynamic Access Control to reduce the complexity of security groups, see the Dynamic Access Control Blog.

Using User Claims

As a rule of thumb, you should use user claims (vs. security group) when:

- You want to be able to use conditions such as User.Project = File.Project in your policy so that you can compress thousands of conditions to a simple expression (avoiding conditions such as File.Project=Cosmos AND User.Memberof(Cosmos_security_group)).
- The user attribute in Active Directory that you are sourcing the user claim from has the appropriate security setting on who or what can set that attribute.
- High integrity of the attribute value in Active Directory and the system that sets this value has operational procedures that take into consideration the use of that value for authorization decisions.
- No foreseeable changes to the values in the attribute. For example if the attribute is a department name and these often change due to re-organization, then it is not fit to be used as a user claim.

When using user claims, you should make sure that you have the appropriate Windows Server 2012 domain controller environment to support these user claims. The two main domains of interest are the User domain and the File Server domain.

- Both domains cannot include Windows Server 2003 (or earlier version) domain controllers.
- Have adequate number of Windows Server 2012 domain controllers in the user domain to support the number of Windows 8 clients deployed in that domain or alternatively set the Windows 8 clients to not require claims in which case having at least one Windows Server 2012 domain controller in the user domain will be sufficient (see more details below
- If the User domain and File Server domain are in a different forest, you need to:
  - Have two-way trust relations between the two forests.
  - Have all forest root domain controllers for both domains be Windows Server 2012

Operations to enable user claims

- Enable the domain controllers to provide claims and compound authentication on request

Enable the domain controllers to provide claims and compound authentication on request

To enable the domain controllers to provide claims and compound authentication on request

1. Open Group Policy Management and navigate to **Domain Controllers** OU in the domain.
2. Right-click the **Default Domain Controllers Policy** and select **Edit**.
3. In the Group Policy Management Editor window, navigate to **Computer Configuration**, > **Administrative Templates**, **System**, and **KDC**.
4. Select **KDC support for claims, compound authentication, and Kerberos armoring**.
5. Under **Claims, compound authentication for Dynamic Access Control and Kerberos armoring** options select **Supported**.
6. Click **OK**. Close Group Policy Management.

Important

Until the Kerberos Group Policy **Kerberos client support for claims, compound authentication and Kerberos armoring** is enabled on all Windows 8 devices, claims and compound authentication will not be requested and claims-based and device-based access will fail.

Warning

Windows 8 devices enabled to support requesting claims and compound authentication will fail authentication when a Windows Server 2012 DC cannot be found in domains configured to support claims and compound authentication.

Considerations for using user claims in the file server discretionary ACLs without using Central Access Policies

Windows Server 2012 File servers have a group policy setting (On/Off/Automatic) that specifies whether it needs to get user claims for user tokens that do not carry claims. This setting is by default set to “automatic” which results in this group policy setting to be turned **On** if there is a central policy that contains user and/or device claims for that file server. If the file server contains local access policy (Discretionary ACLs) that uses user claims, you need to set this group policy to “On” so that the server knows to request claims on behalf of users that do not provide claims when accessing the server (For example, non-Windows 8 clients.

Using Device Claims and Device Security Groups

Windows 8 introduces the concept of compound identity that allows for the user token to include both the user details (ID, security groups and claims) as well as the device details (ID, security groups and claims) so that you can use these details in the authorization decision such as: Only specific users using a specific device can access highly sensitive data.

Much like user claims, device claims are sourced from the device object attribute in Active Directory (claim source) that contains the value of the claim.

Important
Device claims are supported in Windows 8clients only.

Considerations for using static device claims

To configure static device claims the administrator needs to:

- Apply the appropriate security on the device attribute
- Enable the claim definition – This operation will result in the claim to be available in the Kerberos ticket with the value sourced from the device attribute.
- Enable domain controller support for Dynamic Access Control – This operation will result in the directory service returning claims to the KDC and the KDC creating TGTs containing claims
- Apply the appropriate mechanisms to populate the device attribute in Active Directory.
- Set Windows 8 clients and Windows Server 2012 to request compound tokens.

Operations to enable device claims

- Enable the Windows 8 devices in domain to request claims and compound authentication
- Enable the Windows 8 devices to request claims and compound authentication using custom policy
- Enable the Windows 8 device to receive compound authentication

Enable the Windows 8 devices in domain to request claims and compound authentication

To enable the Windows 8 devices to request claims and compound authentication

1.

Note

Apply the group policy on the domain.

Open Group Policy Management and navigate to **Domain**.

2. Right-click the **Default Domain Controllers Policy** and select **Edit**.
3. In the Group Policy Management Editor window, navigate to **Computer Configuration**, > **Administrative Templates**, **System**, and **Kerberos**.
4. Select **Enable KDC support for claims, compound authentication, and Kerberos armoring**.
5. Click **OK**. Close Group Policy Management.

Enable the Windows 8 devices to request claims and compound authentication using custom policy

To enable Windows 8 devices to request claims and compound authentication using custom policy

1.

Note

Apply the group policy on the domain, site, OU or object scope.

Open Group Policy Management and navigate the appropriate policy.

2. Right-click the **Default Domain Controllers Policy** and select **Edit**.
3. In the Group Policy Management Editor window, navigate to **Computer Configuration**, > **Administrative Templates**, **System**, and **Kerberos**.
4. Select **Enable KDC support for claims, compound authentication, and Kerberos armoring**.
5. Click **OK**. Close Group Policy Management.

Enable the Windows 8 device to receive compound authentication

This group policy setting must be applied on the local group policy.

To enable the Windows 8 device to receive compound authentication

1. Open Local Group Policy Editor.
2. In the Local Group Policy window, expand to **Computer Configuration**, expand **Administrative Templates**, expand **System** and click **Kerberos**. Select **Enable** and **Support compound authentication**.
3. Click **OK** and close the Group Policy Management Editor.

Configuring central access policies with different options

As mentioned before, if you are using security groups, you do not have any specific domain consideration other than the need to upgrade your schema to the Windows Server 2012 schema.

If you decide to use user claims or you would like to use user/device compound identity, your deployment design for Windows Server 2012 can be any of the following three configurations:

- **Configuration 1**: Domains providing claims and compound authentication have all Windows Server 2012domain controllers.
- **Configuration 2**: Only user claim-based access control, so file servers retrieve user claims and domains providing claims have Windows Server 2012 DCs in all the file server sites.
- **Configuration 3**: Device-based access control needed, but cannot wait until all domain controllers can be upgraded.

Configuration 1: Domains providing claims and compound authentication have all Windows Server 2012 DCs

This configuration provides complete infrastructure for claims and compound authentication for Dynamic Access Control and is the easiest to support. It requires that:

- If a cross-forest trusts exist, then root domain have all Windows Server 2012 domain controllers.
- Domains that provide claims and compound authentication have all Windows Server 2012 domain controllers
- All Windows 8 devices must be enabled to support requesting claims and compound authentication

Configuring forest root DCs

Simply upgrade all the domain controllers in the forest root to Windows Server 2012 and configure egress and ingress claims transformation.

Note

This will help ensure that claims are not lost from trusted forests. If pre-Windows Server 2012 domain controllers exist, those domain controllers will discard claims which will result in intermittent access control failures. Additionally pre-Windows Server 2012 domain controllers do not transform claims so the claims data is disclosed to all trusting forests

Configuring domains which provide claims and compound authentication

First identify which domains will be providing claims and compound authentication. These will be the account and resource domains. If all the domains in the environment have Windows Server

2012DCs then configure all.If claims-based access is required then claims will need to be provisioned.

Configure each domain which provides compound authentication and claims to DFL and Enable the DCs to support compound authentication and always provide claims.

Configuring devices to request claims and compound authentication

Update the default domain policy to Enable the Windows 8 devices in domain to request claims and compound authentication or Enable the Windows 8 devices to request claims and compound authentication using custom policy which applies to all the Windows 8 computer objects.

Note

This configuration that you set up to enable Windows 8 devices to request claims and compound authentication is ignored by versions of Windows which do not support it.

Configuring resources to receive compound authentication

If the resources are using CAP, then simply apply the CAP. Otherwise, Enable the Windows 8 device to receive compound authentication.

Configuration 2: Only user claim-based access control, so file servers retrieve user claims and domains providing claims have Windows Server 2012 domain controllers in all the file server sites

This configuration provides limited infrastructure for only user claims for Dynamic Access Control. It requires:

- If a cross-forest trusts exist, then root domain has all Windows Server 2012 DCs
- For each domain which provides user claims on request has Windows Server 2012 DCs in the sites with file servers and no Windows Server 2003 domain controllers.
- Enable all Windows 8 file servers to support requesting claims on the behalf of users.

Important

Authentication mechanism assurance-based universal groups and device-based access control are incompatible with file server retrieval of user claims.

Configuring forest root DCs

Simply upgrade all the domain controllers in the forest root to Windows Server 2012 and configure egress and ingress claims transformation.

Note

This will help ensure that claims are not lost from trusted forests. If pre-Windows Server 2012 domain controllers exist, those domain controllers will discard claims which will result in intermittent access control failures. Additionally pre-Windows Server 2012

domain controllers do not transform claims so the claims data is disclosed to all trusting forests

Configuring domains which provides claims and compound authentication

1. First identify which domains will be providing claims and compound authentication. These will be the account and resource domains.
2. Configure and provision claims as explained in Deploy a Central Access Policy (Demonstration Steps)
3. Configure each domain to Enable the domain controllers to provide claims and compound authentication on request.

Configuring file servers to request claims on the behalf of users

If the resources are using a central access policy, then simply apply the policy. Otherwise, Enable the Windows 8 devices to request claims and compound authentication using custom policy which applies to Windows 8 file server computer objects.

Note
This setting is ignored by versions of Windows which do not support it.

Configuration 3: Device-based access control needed, but cannot wait until all domain controllers can be upgraded

This configuration will be unique to your environment and can be difficult to support when Windows 8 devices have different configurations.

General requirements for all environments:

- If across-forest trusts exist, then root domain must have all Windows Server 2012domain controllers
- For each domain which provides claims and compound authentication on request, there cannot be Windows Server 2003 domain controllers
- For resources using device-based access control, receiving compound authentication must be enabled unless a central access policy is being used.

Considerations for using smartcards for Central Access Polices

In Windows 7 and Windows 8 clients, smart card logon is mapped through security groups. In order to create this mapping, the domain administrator needs to:

- Create a security group that will represent the smart card logon.
- Create a mapping from the smart card certificate OID to and smart card security group.
- Domain controllers need to have Windows Server 2008 R2 Domain Functional Level

Note

This group membership will be lost if the server performs S4U2Self on behalf of the user

Best Practices for Deploying Central Access Policies

The following sections provide additional guidance for best practices for delegation of administration, setting up exception mechanisms, and so on.

Delegating of administration for Dynamic Access Control

Ideally, you should delegate permissions for all Dynamic Access Control containers in the forest root of your domain controller. You would need to grant read-write permissions for to specific security groups that have access to certain objects. For example, you can create universal groups like:

- DAC Claim Admins
- DAC Resource Property Admins
- DAC Central Access Rule Admins
- DAC Central Access Policy Admins

You can then delegate the corresponding rights to these groups.

Following are the built-in Dynamic Access Control containers in Windows Server 2012. To access these containers, browse to configuration partition-> system->services->claims configuration.

- Claim Types
- Resource Properties
- Central Access Rules
- Central Access Policies

You can set up delegation of policies from Active Directory Administrative Center (ADAC).

To set up delegation of permissions from ADAC

1. From Server Manager, on the **Tools** menu, select **Active Directory Administrative Center**.
2. Select Dynamic Access Control on the left pane, and select the container that has the object that you want to delegate permissions to. For example, select **Central Access Policies** and select a policy from the list.
3. Right-click and select **Properties**. In the Policy Properties window, select the **Extensions** tab.
4. Select the **Security** tab. Click **Advanced**. In the Advanced Security Settings dialog box, click **Add**. In the Permission entry dialog box, click **Select a Principal** and type the name of the security group to which you want to grant access to. Click OK.
5. In the Permission entry dialog box, select the permissions you want to grant for the group. Click **OK** three times.

Exception Mechanisms for Planning Central Access Policies

Exceptions to the common access rules are a key component of every access policy and in particular a central access policy. For example, if a central policy for the organization protects access to high business impact data (HBI) so that only full-time employees can access this data, what happens if a vendor in the finance department requires access to financial information that is considered to be HBI so that he can do his job?

There are several valid answers ranging from using one security group in the central access policy to grant access to HBI data (which would then allow the vendor in this example to access both financial HBI data and other HBI data such as HR or engineering) to having multiple security groups for exceptions to having per file- or user-specific exception mechanisms.

Exception Mechanism	Central Access Policy scenario	Description	Pros	Cons
Security group	Any access rule where we are OK with providing access to all the information covered by the central access policy when granting the exception Example is a central access rule for department data that implements a safety net over ALL of the departments data (e.g.: Resource.Department=Finance)	One security group managed by the department IT or Information Security personal with a delegation to allow department senior personal to add / remove (manage) users from the group. Content owners from the department will be able to manage the exception group so that they control	Simple to implement Provides a good delegation model with existing tools to manage groups	Exception is wide and grants access to information that might not be relevant for this specific user

Exception Mechanism	Central Access Policy scenario	Description	Pros	Cons
		who can access information to the department data		
Multiple security groups	Central access rule for access to a range of countries with a finite (e.g.: <20) number of permutations where we would like to have each one controlled by a different content owner Example is a central access rule for access to country data Resource.Country = User.Country	A security group for each of the countries. Each security group is managed by the content owners of that country	Simple to implement Provides a good delegation model with existing tools to manage groups	The more groups there are, the more complex the access conditions becomes. Each time a new instance is added (for example, a new country), the administrator needs to create a new group to manage the exception for it

Tools for Deployment

Data Classification Toolkithttp://go.microsoft.com/fwlink/?LinkId=217654: The Data Classification Toolkit for Windows Server 2012 is designed to help organizations identify, classify, and protect data on their file servers. The out-of-the-box classification and rule examples help organizations build and deploy their policies to protect critical information in a cost-effective manner.The toolkit supports both Windows Server 2012 file servers and Windows Server 2008 R2 file servers. In addition to configuring file classification infrastructure, the latest version of the toolkit allows you to manage a Central Access Policy across the file servers in your organization. It provides tools for you to provision user and device claim values, and manage Central Access Policy across the forest to help simplify the configuration process of Dynamic Access Controls in Windows Server 2012. The toolkit also provides a new report template that you can use to review existing Central Access Policy on file shares.

Appendix: Deployment Configurations for Central Access Policies

Deployment Option	Requirements and Configuration Options	Guidance
Using Security Groups	• Windows Server 2012 File Server • A domain with a Windows Server 2012 schema	Using Security Groups for Dynamic Access Control
Using User Claims	• Configuration 2: Only user claim-based access control, so file servers retrieve user claims and domains providing claims have Windows Server 2012 domain controllers in all the file server sites For cross-forest claims deployment, you need a two-way trust been the user domain and a resource domain. For more information, see Deploy Claims Across Forests • Configuration 1: Domains providing claims and compound authentication have all Windows Server 2012 DCs	Using User Claims
Using Device Claims	• Configuration 2: Only user claim-based access control, so file servers retrieve user claims and domains providing claims have Windows Server 2012 domain controllers in all the file server sites • Configuration 1: Domains providing claims and compound authentication have all Windows Server	Using Device Claims and Device Security Groups

Deployment Option	Requirements and Configuration Options	Guidance
	2012 DCs • Configuration 3: Device-based access control needed, but cannot wait until all domain controllers can be upgraded	

Deploy a Central Access Policy (Demonstration Steps)

In this scenario, the finance department security operations is working with central information security to specify the need for a central access policy so that they can protect archived finance information stored on file servers. The archived finance information from each country can be accessed as read-only by finance employees from the same country. A central finance admin group can access the finance information from all countries.

Deploying a central access policy includes the following phases:

Phase	Description
Plan: Identify the need for policy and the configuration required for deployment	Identify the need for a policy and the configuration required for deployment.
Implement: Configure the components and policy	Configure the components and policy.
Deploy the central access policy	Deploy the policy.
Maintain: Change and stage the policy	Policy changes and staging

Set up a test environment

Before you begin, you need to set up lab to test this scenario. The steps for setting up the lab are explained in detail in Appendix B: Setting Up the Test Environment.

Plan: Identify the need for policy and the configuration required for deployment

This section provides the high-level series of steps that aid in the planning phase of your deployment.

<table>
<tr><th></th><th>Step</th><th>Example</th></tr>
<tr><td>1.1</td><td>Business determines that a central access policy is needed</td><td>To protect finance information that is stored on file servers, the finance department security operations is working with central information security to specify the need for a central access policy.</td></tr>
<tr><td>1.2</td><td>Express the access policy</td><td>Finance documents should only be read by members of the Finance department. Members of the Finance department should only access documents in their own country. Only Finance Administrators should have write-access. An exception will be allowed for members of the FinanceException group. This group will have Read access.</td></tr>
<tr><td>1.3</td><td>Express the access policy in Windows Server 2012 constructs</td><td><table>
<tr><td>Targeting:</td><td>• Resource.Department Contains Finance</td></tr>
<tr><td>Access rules:</td><td>• Allow read User.Country=Resource.Country AND User.department = Resource.Department
• Allow Full control User.MemberOf(FinanceAdmin)</td></tr>
<tr><td>Exception:</td><td>Allow read memberOf(FinanceException)</td></tr>
</table></td></tr>
<tr><td>1.4</td><td>Determine the file properties required for the policy</td><td>Tag files with:
• Department
• Country</td></tr>
<tr><td>1.5</td><td>Determine the claim types and groups required for the policy</td><td>Claim types:
• Country
• Department</td></tr>
</table>

	Step	Example
		User groups: • FinanceAdmin • FinanceException
1.6	Determine the servers on which to apply this policy	Apply the policy on all finance file servers.

Implement: Configure the components and policy

This section presents an example that deploys a central access policy for finance documents.

No	Step	Example
2.1	Create claim types	Create the following claim types: • Department • Country
2.2	Create resource properties	Create and enable the following resource properties: • Department • Country
2.3	Configure a central access rule	Create a Finance Documents rule that includes the policy determined in the previous section.
2.4	Configure a central access policy (CAP)	Create a CAP called Finance Policy and add the Finance Documents rule to that CAP.
2.5	Target central access policy to the file servers	Publish the Finance Policy CAP to the file servers.
2.6	Enable KDC Support for claims, compound authentication and Kerberos armoring.	Enable KDC Support for claims, compound authentication and Kerberos armoring for contoso.com.

In the following procedure, you create two claim types: Country and Department.

To create claim types

1. Open Server DC1 in Hyper-V Manager and log on as contoso\administrator, with the

password **pass@word1**.

2. Open Active Directory Administrative Center.
3. Click the **Tree View icon**, expand **Dynamic Access Control**, and then select **Claim Types**.

   Right-click **Claim Types**, click **New**, and then click **Claim Type**.

   Tip

   You can also open a **Create Claim Type:** window from the **Tasks** pane. On the **Tasks** pane, click **New**, and then click **Claim Type**.
4. In the **Source Attribute** list, scroll down the list of attributes, and click **department**. This should populate the **Display name** field with **department**. Click **OK**.
5. In **Tasks** pane, click **New**, and then click **Claim Type**.
6. In the **Source Attribute** list, scroll down the list of attributes, and then click the **c** attribute (Country-Name). In the **Display name** field, type **country**.
7. In the **Suggested Values** section, select **The following values are suggested:**, and then click **Add**.
8. In the **Value** and **Display name** fields, type **US**, and then click **OK**.
9. Repeat the above step. In the **Add a suggest value** dialog box, type **JP** in the **Value** and **Display name** fields, and then click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
New-ADClaimType country -SourceAttribute c -SuggestedValues:@((New-Object
Microsoft.ActiveDirectory.Management.ADSuggestedValueEntry("US","US","")), (New-Object
Microsoft.ActiveDirectory.Management.ADSuggestedValueEntry("JP","JP","")))
New-ADClaimType department -SourceAttribute department
```

Tip

You can use the Windows PowerShell History Viewer in Active Directory Administrative Center to look up the Windows PowerShell cmdlets for each procedure you perform in Active Directory Administrative Center. For more information, see Windows PowerShell History Viewer

The next step is to create resource properties. In the following procedure you create a resource property that is automatically added to the Global Resource Properties list on the domain controller, so that it is available to the file server.

To create and enable pre-created resource properties

1. In the left pane of Active Directory Administrative Center, click **Tree View**. Expand **Dynamic Access Control**, and then select **Resource Properties**.
2. Right-click **Resource Properties**, click **New**, and then click **Reference Resource Property**.

   Tip
   You can also choose a resource property from the **Tasks** pane. Click **New** and then click **Reference Resource Property**.
3. In **Select a claim type to share its suggested values list**, click **country**.
4. In the **Display name** field, type **country**, and then click **OK**.
5. Double-click the **Resource Properties** list, scroll down to the **Department** resource property. Right-click, and then click **Enable**. This will enable the built-in **Department** resource property.
6. In the **Resource Properties** list on the navigation pane of the Active Directory Administrative Center, you will now have two enabled resource properties:
   - Country
   - Department

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
New-ADResourceProperty Country -IsSecured $true -ResourcePropertyValueType MS-DS-MultivaluedChoice -SharesValuesWith country

Set-ADResourceProperty Department_MS -Enabled $true

Add-ADResourcePropertyListMember "Global Resource Property List" -Members Country

Add-ADResourcePropertyListMember "Global Resource Property List" -Members Department_MS
```

The next step is to create central access rules that define who can access resources. In this scenario the business rules are:

- Finance documents can be read only by members of the Finance department.
- Members of the Finance department can access only documents in their own country.
- Only Finance Administrators can have Write access.
- We will allow an exception for members of the FinanceException group. This group will have Read access.
- The administrator and document owner will still have full access.

Or to express the rules with Windows Server 2012 constructs:

Targeting: Resource.Department Contains Finance

Access Rules:

Allow Read User.Country=Resource.Country AND User.department = Resource.Department

Allow Full control User.MemberOf(FinanceAdmin)

Allow Read User.MemberOf(FinanceException)

To create a central access rule

1. In the left pane of the Active Directory Administrative Center, click **Tree View**, select **Dynamic Access Control**, and then click **Central Access Rules**.
2. Right-click **Central Access Rules**, click **New**, and then click **Central Access Rule**.
3. In the **Name** field, type **Finance Documents Rule**.
4. In the **Target Resources** section, click **Edit**, and in the **Central Access Rule** dialog box, click **Add a condition**. Add the following condition:
   [**Resource**] [**Department**] [**Equals**] [**Value**] [**Finance**], and then click **OK**.
5. In the **Permissions** section, select **Use following permissions as current permissions**, click **Edit**, and in the **Advanced Security Settings for Permissions** dialog box click **Add**.

   Note
   Use the following permissions as proposed permissions option lets you create the policy in staging. For more information on how to do this refer to the Maintain: Change and stage the policy section in this topic.
6. In the **Permission entry for Permissions** dialog box, click **Select a principal**, type **Authenticated Users**, and then click **OK**.
7. In the **Permission Entry for Permissions** dialog box, click **Add a condition**, and add the following conditions:
   [**User**] [**country**] [**Any of**] [**Resource**] [**country**]
   Click **Add a condition**.
   [**And**]
   Click [**User**] [**Department**] [**Any of**] [**Resource**] [**Department**]. Set the **Permissions** to **Read**.
8. Click **OK**, and then click **Add**. Click **Select a principal**, type **FinanceAdmin**, and then click **OK**.
9. Select the **Modify, Read and Execute, Read, Write** permissions, and then click **OK**.
10. Click **Add**, click **Select a principal**, type **FinanceException**, and then click **OK**. Select the permissions to be **Read** and **Read and Execute**.
11. Click **OK** three times to finish and return to Active Directory Administrative Center.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
$countryClaimType = Get-ADClaimType country
$departmentClaimType = Get-ADClaimType department
$countryResourceProperty = Get-ADResourceProperty Country
```

```
$departmentResourceProperty = Get-ADResourceProperty
Department
$currentAcl =
"O:SYG:SYD:AR(A;;FA;;;OW)(A;;FA;;;BA)(A;;0x1200a9;;;S-1-5-21-
1787166779-1215870801-2157059049-1113)(A;;0x1301bf;;;S-1-5-
21-1787166779-1215870801-2157059049-
1112)(A;;FA;;;SY)(XA;;0x1200a9;;;AU;((@USER." +
$countryClaimType.Name + " Any_of @RESOURCE." +
$countryResourceProperty.Name + ") && (@USER." +
$departmentClaimType.Name + " Any_of @RESOURCE." +
$departmentResourceProperty.Name + ")))"
$resourceCondition = "(@RESOURCE." +
$departmentResourceProperty.Name + " Contains {`"Finance`"})"
New-ADCentralAccessRule "Finance Documents Rule" -CurrentAcl
$currentAcl -ResourceCondition $resourceCondition
```

Important

In the above cmdlet example, the security identifiers (SIDs) for the group FinanceAdmin and users is determined at creation time and will be different in your example. For example, the provided SID value (S-1-5-21-1787166779-1215870801-2157059049-1113) for the FinanceAdmins needs to be replaced with the actual SID for the FinanceAdmin group that you would need to create in your deployment. You can use Windows PowerShell to look up the SID value of this group, assign that value to a variable, and then use the variable here. For more information, see Windows PowerShell Tip: Working with SIDs.

You should now have a central access rule that allows people to access documents from the same country and the same department. The rule allows the FinanceAdmin group to edit the documents, and it allows the FinanceException group to read the documents. This rule targets only documents classified as Finance.

To add a central access rule to a central access policy

1. In the left pane of the Active Directory Administrative Center, click **Dynamic Access Control**, and then click **Central Access Policies**.
2. In the **Tasks** pane, click **New**, and then click **Central Access Policy**.
3. In **Create Central Access Policy:**, type **Finance Policy** in the **Name** box.
4. In **Member central access rules**, click **Add**.
5. Double-click the **Finance Documents Rule** to the add it to the **Add the following central access rules** list , and then click **OK**.

6. Click **OK** to finish. You should now have a central access policy named Finance Policy.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
New-ADCentralAccessPolicy "Finance Policy" Add-
ADCentralAccessPolicyMember
-Identity "Finance Policy"
-Member "Finance Documents Rule"
```

To apply the central access policy across file servers by using Group Policy

1. On the **Start** screen, in the **Search** box, type **Group Policy Management**. Double-click **Group Policy Management**.

   Tip
   If the **Show Administrative tools** setting is disabled, the **Administrative Tools** folder and its contents will not appear in the **Settings** results.

   Tip
   In your production environment, you should create a File Server Organization Unit (OU) and add all your file servers to this OU, to which you want to apply this policy. You can then create a group policy and add this OU to that policy..

2. In this step, you edit the group policy object you created in Build the domain controller section in the Test Environment to include the central access policy that you created. In the Group Policy Management Editor, navigate to and select the organizational unit in the domain (contoso.com in this example): **Group Policy Management**, **Forest: contoso.com**, **Domains**, **contoso.com**, **Contoso**, **FileServerOU**.
3. Right-click **FlexibleAccessGPO**, and then click **Edit**.
4. In the Group Policy Management Editor window, navigate to **Computer Configuration**, expand **Policies**, expand **Windows Settings**, and click **Security Settings**.
5. Expand **File System**, right-click **Central Access Policy**, and then click **Manage Central access policies**.
6. In the **Central Access Policies Configuration** dialog box, add **Finance Policy**, and then click **OK**.
7. Scroll down to **Advanced Audit Policy Configuration**, and expand it.
8. Expand **Audit Policies**, and select **Object Access**.
9. Double-click **Audit Central Access Policy Staging**. Select all three check boxes and then click **OK**. This step allows the system to receive audit events related to Central Access Staging Policies.
10. Double-click **Audit File System Properties**. Select all three check boxes then click **OK**.

11. Close the Group Policy Management Editor. You have now included the central access policy to the Group Policy.

For a domain's domain controllers to provide claims or device authorization data, the domain controllers need to be configured to support dynamic access control.

To enable support for claims and compound authentication for contoso.com

1. Open Group Policy Management, click **contoso.com**, and then click **Domain Controllers**.
2. Right-click **Default Domain Controllers Policy**, and then click **Edit**.
3. In the Group Policy Management Editor window, double-click **Computer Configuration**, double-click **Policies**, double-click **Administrative Templates**, double-click **System**, and then double-click **KDC**.
4. Double-click **KDC Support for claims, compound authentication and Kerberos armoring**. In the **KDC Support for claims, compound authentication and Kerberos armoring** dialog box, click **Enabled** and select **Supported** from the **Options** drop-down list. (You need to enable this setting to use user claims in central access policies.)
5. Close **Group Policy Management**.
6. Open a command prompt and type `gpupdate /force`.

Deploy the central access policy

	Step	Example
3.1	Assign the CAP to the appropriate shared folders on the file server.	Assign the central access policy to the appropriate shared folder on the file server.
3.2	Verify that access is appropriately configured.	Check the access for users from different countries and departments.

In this step you will assign the central access policy to a file server. You will log onto a file server that is receiving the central access policy that you created the previous steps and assign the policy to a shared folder.

To assign a central access policy to a file server

1. In Hyper-V Manager, connect to server FILE1. Log on to the server by using contoso\administrator with the password: **pass@word1**.
2. Open an elevated command prompt and type: **gpupdate /force**. This ensures that your Group Policy changes take effect on your server.
3. You also need to refresh the Global Resource Properties from Active Directory. Open an

elevated Windows PowerShell window and type `Update-FSRMClassificationpropertyDefinition`. Click ENTER, and then close Windows PowerShell.

Tip

You can also refresh the Global Resource Properties by logging on to the file server. To refresh the Global Resource Properties from the file server, do the following

a. Logon to File Server FILE1 as contoso\administrator, using the password **pass@word1**.

b. Open File Server Resource Manager. To open File Server Resource Manager, click **Start**, type **file server resource manager**, and then click **File Server Resource Manager**.

c. In the File Server Resource Manager, click **File Classification Management** , right-click **Classification Properties** and then click **Refresh**.

4. Open Windows Explorer, and in the left pane, click drive D. Right-click the **Finance Documents** folder, and click **Properties**.
5. Click the **Classification** tab, click **Country**, and then select **US** in the **Value** field.
6. Click **Department**, then select **Finance** in the **Value** field and then click **Apply**.

Note

Remember that the central access policy was configured to target files for the Department of Finance. The previous steps mark all documents in the folder with the Country and Department attributes.

7. Click the **Security** tab, and then click **Advanced**. Click the **Central Policy** tab.

8. Click **Change**, select **Finance Policy** from the drop-down menu, and then click **Apply**. You can see the **Finance Documents Rule** listed in the policy. Expand the item to view all of the permissions that you set when you created the rule in Active Directory.
9. Click **OK** to return to Windows Explorer.

In the next step, you ensure that access is appropriately configured. User accounts need to have the appropriate Department attribute set (set this using Active Directory Administrative Center). The simplest way to view the effective results of the new policy is to use the **Effective Access** tab in Windows Explorer. The **Effective Access** tab shows the access rights for a given user account.

To examine the access for various users

1. In Hyper-V Manager, connect to server FILE1. Log on to the server by using contoso\administrator. Navigate to D:\ in Windows Explorer. Right-click the **Finance Documents** folder, and then click **Properties**.
2. Click the **Security** tab, click **Advanced**, and then click the **Effective Access** tab.
3. To examine the permissions for a user, click **Select a user**, type the user's name, and

then click **View effective access** to see the effective access rights. For example:

- Myriam Delesalle (MDelesalle) is in the Finance department and should have Read access to the folder.
- Miles Reid (MReid) is a member of the FinanceAdmin group and should have Modify access to the folder.
- Esther Valle (EValle) is not in the Finance department; however, she is a member of the FinanceException group and should have Read access.
- Maira Wenzel (MWenzel) is not in the Finance department and is not a member of either the FinanceAdmin or FinanceException group. She should not have any access to the folder.

Notice that the last column named **Access limited by** in the effective access window. This column tells you which gates are effecting the person's permissions. In this case, the Share and NTFS permissions allow all users full control. However, the central access policy restricts access based on the rules you configured earlier.

Maintain: Change and stage the policy

Number	Step	Example
4.1	Configure Device Claims for Clients	Set the group policy setting to enable device claims
4.2	Enable a claim for devices.	Enable the country claim type for devices.
4.3	Add a staging policy to the existing central access rule that you would like to modify.	Modify the Finance Documents Rule to add a staging policy.
4.4	View the results of the staging policy.	Check for Ester Velle's permissions.

To set up group policy setting to enable claims for devices

1. Log on to DC1, open Group Policy Management, click **contoso.com**, click **Default Domain Policy**, right-click and select **Edit**.
2. In the Group Policy Management Editor window, navigate to **Computer Configuration**, **Policies**, **Administrative Templates**, **System**, **Kerberos**.
3. Select **Kerberos client support for claims, compound authentication and Kerberos armoring** and click **Enable**.

To enable a claim for devices

1. Open Server DC1 in Hyper-V Manager and log on as contoso\Administrator, with the password **pass@word1**.
2. From the **Tools** menu, open Active Directory Administrative Center.
3. Click **Tree View**, expand **Dynamic Access Control**, double-click **Claim Types**, and double-click the **country** claim.
4. In **Claims of this type can be issued for the following classes**, select the **Computer** check box. Click **OK**.
   Both the **User** and **Computer** check boxes should now be selected. The country claim can now be used with devices in addition to users.

The next step is to create a staging policy rule. Staging policies can be used to monitor the effects of a new policy entry before you enable it. In the following step, you will create a staging policy entry and monitor the effect on your shared folder.

To create a staging policy rule and add it to the central access policy

1. Open Server DC1 in Hyper-V Manager and log on as contoso\Administrator, with the password **pass@word1**.
2. Open Active Directory Administrative Center.
3. Click **Tree View**, expand **Dynamic Access Control**, and select **Central Access Rules**.
4. Right-click **Finance Documents Rule**, and then click **Properties**.
5. In the **Proposed Permissions** section, select the **Enable permission staging configuration** check box, click **Edit**, and then click **Add**. In the **Permission Entry for Proposed Permissions** window, click the **Select a Principal** link, type **Authenticated Users**, and then click **OK**.
6. Click the **Add a condition** link and add the following condition:
   [**User**] [**country**] [**Any of**] [**Resource**] [**Country**].
7. Click **Add a condition** again, and add the following condition: [**And**]
   [**Device**] [**country**] [**Any of**] [**Resource**] [**Country**]
8. Click **Add a condition** again, and add the following condition. [And]
   [**User**] [**Group**] [**Member of any**] [**Value**](**FinanceException**)
9. To set the FinanceException, group, click **Add items** and in the **Select User, Computer, Service Account, or Group** window, type **FinanceException**.
10. Click **Permissions**, select **Full Control**, and click **OK**.
11. In the Advance Security Settings for Proposed Permissions window, select **FinanceException** and click **Remove**.
12. Click **OK** two times to finish.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-ADCentralAccessRule
-Identity:
"CN=FinanceDocumentsRule,CN=CentralAccessRules,CN=ClaimsConfiguration,CN=Configuration,DC
=Contoso.com"
-ProposedAcl: "O:SYG:SYD:AR(A;;FA;;;BA)(A;;FA;;;SY)(A;;0x1301bf;;;S-1-21=1426421603-
1057776020-1604)"
-Server: "WIN-2R92NN8VKFP.Contoso.com"
```

Note

In the above cmdlet example, the Server value reflects the Server in the test lab environment. You can use the Windows PowerShell History Viewer to look up the Windows PowerShell cmdlets for each procedure you perform in Active Directory Administrative Center. For more information, see Windows PowerShell History Viewer

In this proposed permissions set, members of the FinanceException group will have Full Access to files from their own country when they access them through a device from the same country as the document. Audit entries are available in the File Servers security log when someone from the Finance department attempts to access files. However, security settings are not enforced until the policy is promoted from staging.

In the next procedure, you verify the results of the staging policy. You access the shared folder with a user name that has permissions based on the current rule. Esther Valle (EValle) is a member of FinanceException, and she currently has Read rights. According to our staging policy, EValle should not have any rights.

To verify the results of the staging policy

1. Connect to the File Server FILE1 in Hyper-V Manager and log on as contoso\administrator, with the password **pass@word1**.
2. Open a Command Prompt window and type **gpupdate /force**. This ensures that your Group Policy changes will take effect on your server.
3. In Hyper-V Manager, connect to server CLIENT1. Log off the user who is currently logged on. Restart the virtual machine, CLIENT1. Then log on to the computer by using contoso\EValle pass@word1.
4. Double-click the desktop shortcut to \\FILE1\Finance Documents. EValle should still have access to the files. Switch back to FILE1.
5. Open **Event Viewer** from the shortcut on the desktop. Expand **Windows Logs**, and then select **Security**. Open the entries with **Event ID 4818** under the **Central Access Policy Staging** task category. You will see that EValle was allowed access; however, according to the staging policy, the user would have been denied access.

Next Steps

If you have a central server management system such as System Center Operations Manager, you can also configuring monitoring for events. This allows Administrators to monitor the effects of central access policies before enforcing them.

Deploy Claims Across Forests

In Windows Server 2012, a claim type is an assertion about the object with which it's associated. Claim types are defined per forest in Active Directory. There are many scenarios where a security principal may need to traverse a trust boundary to access resources in a trusted forest. Cross-forest claims transformation in Windows Server 2012 enables you to transform egress and ingress claims that traverse forests so that the claims are recognized and accepted in the trusting and trusted forests. Some of the real-world scenarios for transformation of claims are:

- Trusting forests can use claim transformation as a guard against elevation of privilege by filtering the incoming claims with specific values.

  Trusting forests can also issue claims for principals coming over a trust boundary if the trusted forest does not support or issue any claims.
- Trusted forests can use claim transformation to prevent certain claim types and claims with certain values from going out to the trusting forest.
- You can also use claim transformation to map different claim types between trusting and trusted forests. This can be used to generalize the claim-type, the claim value, or both. Without this, you need to standardize the data between the forests before you can use the claims. Generalizing claims between the trusting and trusted forests reduces the IT costs.

Claim transformation rules

The transformation rule language syntax divides a single rule into two main parts: a series of condition statements and the issue statement. Each condition statement has two subcomponents: the claim identifier and the condition. The issue statement contains keywords, delimiters, and an issue expression. The condition statement optionally begins with a claim identifier variable, which represents the matched input claim. The condition checks for the expression. If the input claim does not match the condition, then the transformation engine ignores the issue statement and evaluates the next input claim against the transformation rule. If all conditions match the input claim, it processes the issue statement.

For detailed information on claim rules language, see Claims Transformation Rules Language.

Linking claim transformation policies to forests

There are two components involved in setting up claim transformation policies: claim transformation policy objects and the transformation link. The policy objects live in the

configuration naming context in a forest, and they contain mapping information for the claims. The link specifies which trusting and trusted forests the mapping applies to.

It is important to understand if the forest is the trusting or trusted forest because this is basis for linking transformation policy objects. For example, the trusted forest is the forest that contains user accounts that require access. The trusting forest is the forest that contains resources that you want to give users access to. Claims travel in the same direction as the security principal that requires access. For example, if there is a one-way trust from the contoso.com forest to the adatum.com forest, the claims will flow from adatum.com to contoso.com, which allows users from adatum.com to access resources in contoso.com.

By default, a trusted forest allows all outgoing claims to pass, and a trusting forest drops all incoming claims that it receives.

In this scenario

The following guidance is available for this scenario:

- Deploy Claims Across Forests (Demonstration Steps)
- Claims Transformation Rules Language

Roles and features included in this scenario

The following table lists the roles and features that are part of this scenario and describes how they support it.

Role/feature	How it supports this scenario
Active Directory Domain Services	In this scenario, you are required to set up two Active Directory forests with a two-way trust. You have claims in both forests. You also set central access policies on the trusting forest where the resources reside.
File and Storage Services role	In this scenario, the data classification is applied to the resources on the file servers. The central access policy is applied to the folder where you want to grant user access. After transformation, the claim grants user access to resources based on the central access policy that is applied to the folder on the file server.

Deploy Claims Across Forests (Demonstration Steps)

In this topic, we'll cover a basic scenario that explains how to configure claims transformations between trusting and trusted forests. You will learn how claims transformation policy objects can be created and linked to the trust on the trusting forest and the trusted forest. You will then validate the scenario.

Scenario overview

Adatum Corporation provides financial services to Contoso, Ltd. Each quarter, Adatum accountants copy their account spreadsheets to a folder on a file server located at Contoso, Ltd. There is a two-way trust set up from Contoso to Adatum. Contoso, Ltd. wants to protect the share so that only Adatum employees can access the remote share.

In this scenario:

1. Set up the prerequisites and the test environment
2. Set up claims transformation on trusted forest (Adatum)
3. Set up claims transformation in the trusting forest (Contoso)
4. Validate the scenario

Set up the prerequisites and the test environment

The test configuration involves setting up two forests: Adatum Corporation and Contoso, Ltd, and having a two-way trust between Contoso and Adatum. "adatum.com" is the trusted forest and "contoso.com" is the trusting forest.

The claims transformation scenario demonstrates transformation of a claim in the trusted forest to a claim in the trusting forest. To do this, you need to set up a new forest called adatum.com and populate the forest with a test user with a company value of "Adatum". You then have to set up a two-way trust between contoso.com and adatum.com.

Important

When setting up the Contoso and Adatum forests, you must ensure that both the root domains are at the Windows Server 2012 Domain Functional Level for claims transformation to work.

You need to set up the following for the lab. These procedures are explained in detail in Appendix B: Setting Up the Test Environment

You need to implement the following procedures to set up the lab for this scenario:

1. **Set Adatum as trusted forest to Contoso**
2. Create the "Company" claim type on Contoso

3. Enable the “Company” resource property on Contoso
4. Create the central access rule
5. Create the central access policy
6. Publish the new policy through Group Policy
7. Create the Earnings folder on the file server
8. Set classification and apply the central access policy on the new folder

Use the following information to complete this scenario:

Objects	Details
Users	Jeff Low, Contoso
User claims on Adatum and Contoso	ID: ad://ext/Company:ContosoAdatum, Source attribute: company Suggested values: Contoso, Adatum **Important** You must set the ID on the “Company” claim type on both Contoso and Adatum to be the same for the claims transformation to work.
Central access rule on Contoso	AdatumEmployeeAccessRule
Central access policy on Contoso	Adatum Only Access Policy
Claims Transformation policies on Adatum and Contoso	DenyAllExcept Company
File folder on Contoso	D:\EARNINGS

Set up claims transformation on trusted forest (Adatum)

In this step you create a transformation policy in Adatum to deny all claims except “Company” to pass to Contoso.

The Active Directory module for Windows PowerShell provides the **DenyAllExcept** argument, which drops everything except the specified claims in the transformation policy.

To set up a claims transformation, you need to create a claims transformation policy and link it between the trusted and trusting forests.

Create a claims transformation policy in Adatum

To create a transformation policy Adatum to deny all claims except “Company”

1. Sign in to the domain controller, adatum.com as Administrator with the password **pass@word1**.
2. Open an elevated command prompt in Windows PowerShell, and type the following:

```
New-ADClaimTransformPolicy `
-Description:"Claims transformation policy to deny all claims
except Company"`
-Name:"DenyAllClaimsExceptCompanyPolicy" `
-DenyAllExcept:company `
-Server:"adatum.com" `
```

Set a claims transformation link on Adatum’s trust domain object

In this step, you apply the newly created claims transformation policy on Adatum’s trust domain object for Contoso.

To apply the claims transformation policy

1. Sign in to the domain controller, adatum.com as Administrator with the password **pass@word1**.
2. Open an elevated command prompt in Windows PowerShell, and type the following:

```
Set-ADClaimTransformLink `
-Identity:"contoso.com" `
-Policy:"DenyAllClaimsExceptCompanyPolicy" `
-TrustRole:Trusted `
```

Set up claims transformation in the trusting forest (Contoso)

In this step you create a claims transformation policy in Contoso (the trusting forest) to deny all claims except “Company.” You need to create a claims transformation policy and link it to the forest trust.

Create a claims transformation policy in Contoso

To create a transformation policy Adatum to deny all except “Company”

1. Sign in to the domain controller, contoso.com as Administrator with the password **pass@word1**.
2. Open an elevated command prompt in Windows PowerShell and type the following:

```
New-ADClaimTransformPolicy `
-Description:"Claims transformation policy to deny all claims
except company" `
-Name:"DenyAllClaimsExceptCompanyPolicy" `
-DenyAllExcept:company `
-Server:"contoso.com" `
```

Set a claims transformation link on Contoso’s trust domain object

In this step, you apply the newly created claims transformation policy on the contoso.com trust domain object for Adatum to allow “Company” be passed through to contoso.com. The trust domain object is named adatum.com.

To set the claims transformation policy

1. Sign in to the domain controller, contoso.com as Administrator with the password **pass@word1**.
2. Open an elevated command prompt in Windows PowerShell and type the following:

```
Set-ADClaimTransformLink
-Identity:"adatum.com" `
-Policy:"DenyAllClaimsExceptCompanyPolicy" `
-TrustRole:Trusting `
```

Validate the scenario

In this step you try to access the D:\EARNINGS folder that was set up on the file server FILE1 to validate that the user has access to the shared folder.

To ensure that the Adatum user can access the shared folder

1. Sign in to the Client machine, CLIENT1 as Jeff Low with the password **pass@word1**.
2. Browse to the folder \\FILE1.contoso.com\Earnings.
3. Jeff Low should be able to access the folder.

Additional scenarios for claims transformation policies

Following is a list of additional common cases in claims transformation.

Scenario	Policy

Allow all claims that come from Adatum to go through to Contoso Adatum	`New-ADClaimTransformPolicy ` `-Description:"Claims transformation policy to allow all claims" ` `-Name:"AllowAllClaimsPolicy" ` `-AllowAll ` `-Server:"contoso.com" `
	
	`Set-ADClaimTransformLink ` `-Identity:"adatum.com" ` `-Policy:"AllowAllClaimsPolicy" ` `-TrustRole:Trusting ` `-Server:"contoso.com" `

Deny all claims that come from Adatum to go through to Contoso Adatum	`New-ADClaimTransformPolicy ` `-Description:"Claims transformation policy to deny all claims" ` `-Name:"DenyAllClaimsPolicy" ` `-DenyAll ` `-Server:"contoso.com" `

Scenario	Policy
	`Set-ADClaimTransformLink ` `-Identity:"adatum.com" ` `-Policy:"DenyAllClaimsPolicy" ` `-TrustRole:Trusting ` `-Server:"contoso.com"`
Allow all claims that come from Adatum except “Company” and “Department” to go through to Contoso Adatum	`New-ADClaimTransformationPolicy ` `-Description:"Claims transformation policy to allow all claims except company and department" ` `-Name:"AllowAllClaimsExceptCompanyAndDepartmentPolicy" ` `-AllowAllExcept:company,department ` `-Server:"contoso.com" ` `Set-ADClaimTransformLink ` `-Identity:"adatum.com" ` `-Policy:"AllowAllClaimsExceptCompanyAndDepartmentPolicy" ` `-TrustRole:Trusting ` `-Server:"contoso.com" `

- Dynamic Access Control: Scenario Overview

Claims Transformation Rules Language

The across-forest claims transformation feature enables you to bridge claims for Dynamic Access Control across forest boundaries by setting claims transformation policies on across-forest trusts. The primary component of all policies is rules that are written in claims transformation rules language. This topic provides details about this language and provides guidance about authoring claims transformation rules.

The Windows PowerShell cmdlets for transformation policies on across-forest trusts have options to set simple policies that are required in common scenarios. These cmdlets translate the user input into policies and rules in the claims transformation rules language, and then store them in Active Directory in the prescribed format. For more information about cmdlets for claims transformation, see the AD DS Cmdlets for Dynamic Access Control.

Depending on the claims configuration and the requirements placed on the across-forest trust in your Active Directory forests, your claims transformation policies may have to be more complex than the policies supported by the Windows PowerShell cmdlets for Active Directory. To effectively author such policies, it is essential to understand the claims transformation rules language syntax and semantics. This claims transformation rules language ("the language") in Active Directory is a subset of the language that is used by Active Directory Federation Services for similar purposes, and it has a very similar syntax and semantics. However, there are fewer operations allowed, and additional syntax restrictions are placed in the Active Directory version of the language.

This topic briefly explains the syntax and semantics of the claims transformation rules language in Active Directory and considerations to be made when authoring policies. It provides several sets of example rules to get you started, and examples of incorrect syntax and the messages they generate, to help you decipher error messages when you author the rules.

Tools for authoring claims transformation policies

Windows PowerShell cmdlets for Active Directory: This is the preferred and recommended way to author and set claims transformation policies. These cmdlets provide switches for simple policies and verify rules that are set for more complex policies.

LDAP: Claims transformation policies can be edited in Active Directory through Lightweight Directory Access Protocol (LDAP). However, this is not recommended because the policies have several complex components, and the tools you use may not validate the policy before writing it to Active Directory. This may subsequently require a considerable amount of time to diagnose problems.

Active Directory claims transformation rules language

Syntax overview

Here is a brief overview of the syntax and semantics of the language:

- The claims transformation rule set consists of zero or more rules. Each rule has two active parts: **Select Condition List** and **Rule Action**. If the **Select Condition List** evaluates to TRUE, the corresponding rule action is executed.
- **Select Condition List** has zero or more **Select Conditions**. All of the **Select Conditions** must evaluate to TRUE for the **Select Condition List** to evaluate to TRUE.
- Each **Select Condition** has a set of zero or more **Matching Conditions**. All the **Matching Conditions** must evaluate to TRUE for the Select Condition to evaluate to TRUE. All of these conditions are evaluated against a single claim. A claim that matches a **Select Condition** can be tagged by an **Identifier** and referred to in the **Rule Action**.
- Each **Matching Condition** specifies the condition to match the **Type** or **Value** or **ValueType** of a claim by using different **Condition Operators** and **String Literals**.
    - When you specify a **Matching Condition** for a **Value**, you must also specify a **Matching Condition** for a specific **ValueType** and vice versa. These conditions must be next to each other in the syntax.
    - **ValueType** matching conditions must use specific **ValueType** literals only.
- A **Rule Action** can copy one claim that is tagged with an **Identifier** or issue one claim based on a claim that is tagged with an Identifier and/or given String Literals.

Example rule

This example shows a rule that can be used to translate the claims Type between two forests, provided that they use the same claims ValueTypes and have the same interpretations for claims Values for this type. The rule has one matching condition and an Issue statement that uses String Literals and a matching claims reference.

```
C1: [TYPE=="EmployeeType"]
                  => ISSUE (TYPE= “EmpType”, VALUE = C1.VALUE, VALUETYPE = C1.VALUETYPE);
```

`[TYPE=="EmployeeType"] == Select Condition List with one Matching Condition for claims Type.`

`ISSUE (TYPE= “EmpType”, VALUE = C1.VALUE, VALUETYPE = C1.VALUETYPE) == Rule Action that issues a claims using string literal and matching claim referred with the Identifier.`

Runtime operation

It is important to understand the runtime operation of claims transformations to author the rules effectively. The runtime operation uses three sets of claims:

1. **Input claims set**: The input set of claims that are given to the claims transformation operation.
2. **Working claims set**: Intermediate claims that are read from and written to during the claims transformation.
3. **Output claims set**: Output of the claims transformation operation.

Here is a brief overview of the runtime claims transformation operation:

1. Input claims for claims transformation are used to initialize the working claims set.
   a. When processing each rule, the working claims set is used for the input claims.
   b. The Selection Condition List in a rule is matched against all possible sets of claims from the working claims set.
   c. Each set of matching claims is used to run the action in that rule.
   d. Running a rule action results in one claim, which is appended to the output claims set and the working claims set. Thus, the output from a rule is used as input for subsequent rules in the rule set.
2. The rules in the rule set are processed in sequential order starting with the first rule.
3. When the entire rule set is processed, the output claims set is processed to remove duplicate claims and for other security issues. The resulting claims are the output of the claims transformation process.

It is possible to write complex claims transformations based on the previous runtime behavior.

Example: Runtime operation

This example shows the runtime operation of a claims transformation that uses two rules.

```
     C1:[Type==”EmpType”, Value==”FullTime”,ValueType==”string”] =>
                Issue(Type==”EmployeeType”, Value==”FullTime”,ValueType==”string”);
     [Type==”EmployeeType”] =>
               Issue(Type==”AccessType”, Value==”Privileged”, ValueType==”string”);
Input claims and Initial Evaluation Context:
  {(Type= “EmpType”),(Value=”FullTime”),(ValueType=”String”)}
{(Type= “Organization”),(Value=”Marketing”),(ValueType=”String”)}
After Processing Rule 1:
 Evaluation Context:
  {(Type= “EmpType”),(Value=”FullTime”),(ValueType=”String”)}
{(Type= “Organization”), (Value=”Marketing”),(ValueType=”String”)}
  {(Type= “EmployeeType”),(Value=”FullTime”),(ValueType=”String”)}
Output Context:
  {(Type= “EmployeeType”),(Value=”FullTime”),(ValueType=”String”)}
```

```
After Processing Rule 2:

Evaluation Context:

  {(Type= “EmpType”),(Value=”FullTime”),(ValueType=”String”)}

{(Type= “Organization”),(Value=”Marketing”),(ValueType=”String”)}

  {(Type= “EmployeeType”),(Value=”FullTime”),(ValueType=”String”)}

  {(Type= “AccessType”),(Value=”Privileged”),(ValueType=”String”)}

Output Context:

  {(Type= “EmployeeType”),(Value=”FullTime”),(ValueType=”String”)}

  {(Type= “AccessType”),(Value=”Privileged”),(ValueType=”String”)}

Final Output:

  {(Type= “EmployeeType”),(Value=”FullTime”),(ValueType=”String”)}

  {(Type= “AccessType”),(Value=”Privileged”),(ValueType=”String”)}
```

Special rules semantics

The following are special syntax for rules:

1. Empty Rule Set == No Output Claims
2. Empty Select Condition List == Every Claim matches the Select Condition List

   Example: Empty Select Condition List

   The following rule matches every claim in the working set.

   ```
   => Issue (Type = “UserType”, Value = “External”, ValueType =
   “string”)
   ```
3. Empty Select Matching List == Every claim matches the Select Condition List

   Example: Empty Matching Conditions

   The following rule matches every claim in the working set. This is the basic “Allow-all” rule if it is used alone.

   ```
   C1:[] => Issule (claim = C1);
   ```

Security considerations

Claims that enter a forest

The claims presented by principals that are incoming to a forest need to be inspected thoroughly to ensure that we allow or issue only the correct claims. Improper claims can compromise the forest security, and this should be a top consideration when authoring transformation policies for claims that enter a forest.

Active Directory has the following features to prevent misconfiguration of claims that enter a forest:

- If a forest trust has no claims transformation policy set for the claims that enter a forest, for security purposes, Active Directory drops all the principal claims that enter the forest.
- If running the rule set on claims that enters a forest results in claims that are not defined in the forest, the undefined claims are dropped from the output claims.

Claims that leave a forest

Claims that leave a forest present a lesser security concern for the forest than the claims that enter the forest. Claims are allowed to leave the forest as-is even when there is no corresponding claims transformation policy in place. It is also possible to issue claims that are not defined in the forest as part of transforming claims that leave the forest. This is to easily set up across-forest trusts with claims. An administrator can determine if claims that enter the forest need to be transformed, and set up the appropriate policy. For example, an administrator could set a policy if there is a need to hide a claim to prevent information disclosure.

Syntax errors in claims transformation rules

If a given claims transformation policy has a rules set that is syntactically incorrect or if there are other syntax or storage issues, the policy is considered invalid. This is treated differently than the default conditions mentioned earlier.

Active Directory is unable to determine the intent in this case and goes into a fail-safe mode, where no output claims are generated on that trust+direction of traversal. Administrator intervention is required to correct the issue. This could happen if LDAP is used to edit the claims transformation policy. Windows PowerShell cmdlets for Active Directory have validation in place to prevent writing a policy with syntax issues.

Other language considerations

1. There are several key words or characters that are special in this language (referred to as terminals). These are presented in the Language terminals table later in this topic. The error messages use the tags for these terminals for disambiguation.
2. Terminals can sometimes be used as string literals. However, such usage may conflict with the language definition or have unintended consequences. This kind of usage is not recommended.
3. The rule action cannot perform any type conversions on claim Values, and a rule set that contains such a rule action is considered invalid. This would cause a runtime error, and no output claims are produced.
4. If a rule action refers to an Identifier that was not used in the Select Condition List portion of the rule, it is an invalid usage. This would cause a syntax error.

Example: Incorrect Identifier reference
The following rule illustrates an incorrect Identifier used in rule action.

```
C1:[] => Issue (claim = C2);
```

Sample transformation rules

- **Allow all claims of a certain type**

  Exact type

  ```
  C1:[type==”XYZ”] => Issue (claim = C1);
  ```

  Using Regex

  ```
  C1: [type =~ “XYZ*”] => Issue (claim = C1);
  ```

- **Disallow a certain claim type**

  Exact type

  ```
  C1:[type != “XYZ”] => Issue (claim=C1);
  ```

  Using Regex

  ```
  C1:[Type !~ “XYZ?”] => Issue (claim=C1);
  ```

Examples of rules parser errors

Claims transformation rules are parsed by a custom parser to check for syntax errors. This parser is run by related Windows PowerShell cmdlets before storing rules in Active Directory. Any errors in parsing the rules, including syntax errors, are printed on the console. Domain controllers also run the parser before using the rules for transforming claims, and they log errors in the event log (add event log numbers).

This section illustrates some examples of rules that are written with incorrect syntax and the corresponding syntax errors that are generated by the parser.

1. Example:

   ```
   c1;[]=>Issue(claim=c1);
   ```

   This example has an incorrectly used semicolon in place of a colon.
   Error message:
   POLICY0002: Could not parse policy data.
   Line number: 1, Column number: 2, Error token: ;. Line: 'c1;[]=>Issue(claim=c1);'.
   Parser error: 'POLICY0030: Syntax error, unexpected ';', expecting one of the following: ':' .'

2. Example:

   ```
   c1:[]=>Issue(claim=c2);
   ```

In this example, the Identifier tag in the copy issuance statement is undefined.
Error message:
POLICY0011: No conditions in the claim rule match the condition tag specified in the CopyIssuanceStatement: 'c2'.

3. Example:

```
c1:[type=="x1", value=="1", valuetype=="bool"]=>Issue(claim=c1)
```

"bool" is not a Terminal in the language, and it is not a valid ValueType. Valid terminals are listed in the following error message.
Error message:
POLICY0002: Could not parse policy data.
Line number: 1, Column number: 39, Error token: "bool". Line: 'c1:[type=="x1", value=="1",valuetype=="bool"]=>Issue(claim=c1);'.
Parser error: 'POLICY0030: Syntax error, unexpected 'STRING', expecting one of the following: 'INT64_TYPE' 'UINT64_TYPE' 'STRING_TYPE' 'BOOLEAN_TYPE' 'IDENTIFIER'

4. Example:

```
c1:[type=="x1", value==1,
valuetype=="boolean"]=>Issue(claim=c1);
```

The numeral **1** in this example is not a valid token in the language, and such usage is not allowed in a matching condition. It has to be enclosed in double quotes to make it a string.
Error message:
POLICY0002: Could not parse policy data.
Line number: 1, Column number: 23, Error token: 1. Line: 'c1:[type=="x1", value==1, valuetype=="bool"]=>Issue(claim=c1);'.Parser error: 'POLICY0029: Unexpected input.

5. Example:

```
c1:[type == "x1", value == "1", valuetype == "boolean"] =>

      Issue(type = c1.type, value="0", valuetype == "boolean");
```

This example used a double equal sign (==) instead of a single equal sign (=).
Error message:
POLICY0002: Could not parse policy data.
Line number: 1, Column number: 91, Error token: ==. Line: 'c1:[type=="x1", value=="1", valuetype=="boolean"]=>Issue(type=c1.type, value="0", valuetype=="boolean");'.
Parser error: 'POLICY0030: Syntax error, unexpected '==', expecting one of the following: '='

6. Example:

```
c1:[type=="x1", value=="boolean", valuetype=="string"] =>
```

```
Issue(type=c1.type, value=c1.value, valuetype = "string");
```

This example is syntactically and semantically correct. However, using “boolean” as a string value is bound to cause confusion, and it should be avoided. As previously mentioned, using language terminals as claims values should be avoided where possible.

Language terminals

The following table lists the complete set of terminal strings and the associated language terminals that are used in the claims transformation rules language. These definitions use case-insensitive UTF-16 strings.

String	Terminal
"=>"	IMPLY
";"	SEMICOLON
":"	COLON
","	COMMA
"."	DOT
"["	O_SQ_BRACKET
"]"	C_SQ_BRACKET
"("	O_BRACKET
")"	C_BRACKET
"=="	EQ
"!="	NEQ
"=~"	REGEXP_MATCH
"!~"	REGEXP_NOT_MATCH
"="	ASSIGN
"&&"	AND
"issue"	ISSUE
"type"	TYPE
"value"	VALUE
"valuetype"	VALUE_TYPE
"claim"	CLAIM

String	Terminal
"[_A-Za-z][_A-Za-z0-9]*"	IDENTIFIER
"\"[^\"\n]*\""	STRING
"uint64"	UINT64_TYPE
"int64"	INT64_TYPE
"string"	STRING_TYPE
"boolean"	BOOLEAN_TYPE

Language syntax

The following claims transformation rules language is specified in ABNF form. This definition uses the terminals that are specified in the previous table in addition to the ABNF productions defined here. The rules must be encoded in UTF-16, and the string comparisons must be treated as case insensitive.

```
Rule_set        = ;/*Empty*/
             / Rules
Rules         = Rule
             / Rule Rules
Rule          = Rule_body

claim_value_assign   = (claim_val_assign COMMA claim_val_type_assign)
             /(claim_val_type_assign COMMA claim_val_assign)
claim_val_assign    = VALUE ASSIGN Expr
```

```
claim_val_type_assign = VALUE_TYPE ASSIGN Value_type_expr

Claim_type_assign   = TYPE ASSIGN Expr
```

Scenario: File Access Auditing

Security Auditing is one of the most powerful tools to help maintain the security of an enterprise. One of the key goals of security audits is regulatory compliance. Industry standards such as Sarbanes Oxley, Health Insurance Portability and Accountability Act (HIPAA), and Payment Card Industry (PCI) require enterprises to follow a strict set of rules related to data security and privacy. Security audits help establish the presence of such policies and prove compliance with these standards. Additionally, security audits help detect anomalous behavior, identify and mitigate gaps in security policies, and deter irresponsible behavior by creating a trail of user activity that can be used for forensic analysis.

Audit policy requirements are typically driven at the following levels:

- **Information security.** File access audit trails are often used for forensic analysis and intrusion detection. Being able to get targeted events about access to high-value information lets organizations considerably improve their response time and investigation accuracy.
- **Organizational policy.** For example, organizations regulated by PCI standards could have a central policy to monitor access to all files that are marked as containing credit card information and personally identifiable information (PII).
- **Departmental policy.** For example, the finance department may require that the ability to modify certain finance documents (such as a quarterly earnings report) be restricted to the finance department, and thus the department would want to monitor all other attempts to change these documents.
- **Business policy.** For example, business owners may want to monitor all unauthorized attempts to view data that belongs to their projects.

Additionally, the compliance department may want to monitor all changes to central authorization policies and policy constructs such as user, computer, and resource attributes.

One of the biggest considerations of security audits is the cost of collecting, storing, and analyzing audit events. If the audit policies are too broad, the volume of audit events collected rises, and this increases costs. If the audit policies are too narrow, you risk missing important events.

With Windows Server 2012, you can author audit policies by using claims and resource properties. This leads to richer, more targeted, and easier-to-manage audit policies. It enables scenarios that, until now, were impossible or too difficult to perform. The following are examples of audit policies that administrators can author:

- Audit everyone who does not have a high-security clearance and tries to access an HBI document. For example, Audit | Everyone | All-Access | Resource.BusinessImpact=HBI AND User.SecurityClearance!=High.

- Audit all vendors when they try to access documents that are related to projects that they are not working on. For example, Audit | Everyone | All-Access | User.EmploymentStatus=Vendor AND User.Project Not_AnyOf Resource.Project.

These policies help regulate the volume of audit events and limit them to only the most relevant data or users.

After administrators have created and applied the audit policies, the next consideration for them is gleaning meaningful information from the audit events that they collected. Expression-based audit events help reduce the volume of audits. However, users need a way to query these events for meaningful information and ask questions such as, “Who is accessing my HBI data?” or “Was there an unauthorized attempt to access sensitive data?”

Windows Server 2012 enhances existing data access events with user, computer, and resource claims. These events are generated on a per-server basis. To provide a full view of events across the organization, Microsoft is working with partners to provide event collection and analysis tools, such as the Audit Collection Services in System Center Operation Manager .

Figure 4 shows an overview of a central audit policy.

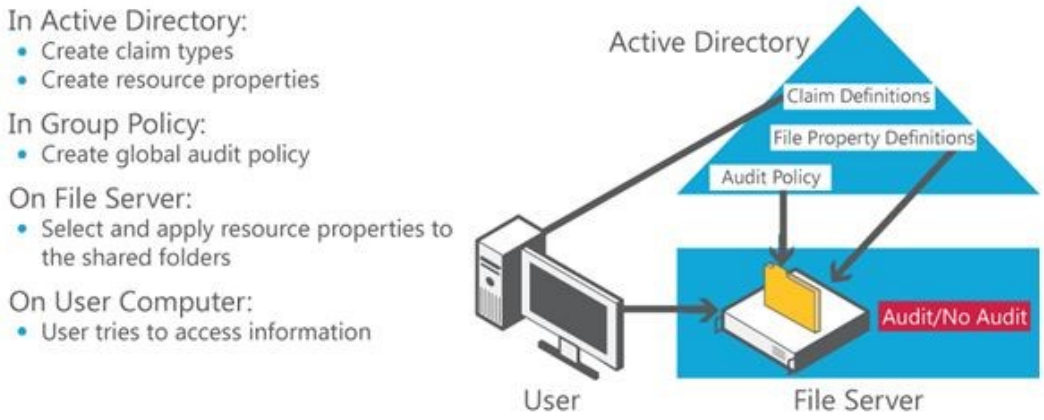

Figure 4 Central auditing experiences

Setting up and consuming security audits typically involves the following general steps:

1. Identify the correct set of data and users to monitor
2. Create and apply appropriate audit policies
3. Collect and analyze audit events
4. Manage and monitor the policies that were created

In this scenario

The following topics provide additional guidance for this scenario:

- Plan for File Access Auditing
- Deploy Security Auditing with Central Audit Policies (Demonstration Steps)

Roles and features included in this scenario

The following table lists the roles and features that are part of this scenario and describes how they support it.

Role/feature	How it supports this scenario
Active Directory Doman Services role	AD DS in Windows Server 2012 introduces a claims-based authorization platform that enables creating user claims and device claims, compound identity, (user plus device claims), new central access policies (CAP) model, and the use of file classification information in authorization decisions.
File and Storage Services role	File servers in Windows Server 2012 provide a user interface where administrators can view the effective permissions for users for a file or folder and troubleshoot access issues and grant access as required.

Plan for File Access Auditing

The information in this topic explains the security auditing enhancements that are introduced in Windows Server 2012 and new audit settings that you should consider as you deploy Dynamic Access Control in your enterprise. The actual audit policy settings that you deploy will depend on your goals, which can include regulatory compliance, monitoring, forensic analysis, and troubleshooting.

Note
Detailed information about how to plan and deploy an overall security auditing strategy for your enterprise is explained in Planning and Deploying Advanced Security Audit Policies. For more information about configuring and deploying a security audit policy, see the Advanced Security Audit Policy Step-by-Step Guide.

The following security auditing capabilities in Windows Server 2012 can be used with Dynamic Access Control to extend your overall security auditing strategy.

- **Expression-based audit policies**. Dynamic Access Control enables you to create targeted audit policies by using expressions based on user, computer, and resource claims. For example, you could create an audit policy to track all Read and Write operations on files classified as high-business impact by employees who do not have a high-security clearance. Expression-based audit policies can be authored directly for a file or folder or centrally through Group Policy. For more information, see Group Policy using Global Object Access Auditing.

- **Additional information from object access auditing**. File access auditing is not new to Windows Server 2012. With the right audit policy in place, the Windows and Windows Server operating systems generate an audit event each time a user accesses a file. Existing File Access events (4656, 4663) contain information about the attributes of the file that was accessed. This information can be used by event log filtering tools to help you identify the most relevant audit events. For more information, see Audit Handle Manipulation and Audit Security Accounts Manager.
- **More information from user logon events**. With the right audit policy in place, Windows operating systems generate an audit event every time a user signs in to a computer locally or remotely. In Windows Server 2012 or Windows 8, you can also monitor user and device claims associated with a user's security token. Examples can include Department, Company, Project, and Security clearances.Event 4626 contains information about these user claims and device claims, which can be leveraged by audit log management tools to correlate user logon events with object access events to enable event filtering based on file attributes and user attributes. For more information about user logon auditing, see Audit Logon.
- **Change tracking for new types of securable objects**. Tracking changes to securable objects can be important in the following scenarios:
    - **Change tracking for central access policies and central access rules**. Central access policies and central access rules define the central policy that can be used to control access to critical resources. Any change to these can directly impact the file access permissions that are granted to users on multiple computers. Therefore, tracking changes to central access policies and central access rules can be important for your organization. Because central access policies and central access rules are stored in Active Directory Domain Services (AD DS), you can audit attempts to modify them, like auditing changes to any other securable object in AD DS. For more information, see Audit Directory Service Access.
    - **Change tracking for definitions in the claim dictionary**. Claim definitions include the claim name, description, and possible values. Any change to the claim definition can impact the access permissions on critical resources. Therefore, tracking changes to claim definitions can be important to your organization. Like central access policies and central access rules, claim definitions are stored in AD DS; therefore, they can be audited like any another securable object in AD DS. For more information, see Audit Directory Service Access.
    - **Change tracking for file attributes**. File attributes determine which central access rule applies to the file. A change to the file attributes can potentially impact the access restrictions on the file. Therefore, it can be important to track changes to file attributes. You can track changes to file attributes on any computer by configuring the authorization policy change auditing policy. For more information, see Authorization Policy Change auditing and Object Access auditing for File Systems. In Windows Server 2012, Event 4911 differentiates file attribute policy changes from other authorization policy change events.
    - **Chang tracking for the central access policy associated with a file.** Event 4913 displays the security identifiers (SIDs) of the old and new central access policies. Each central access policy also has a user friendly name that can be looked up using this security identifier. For more information, see Authorization Policy Change auditing.

- **Change tracking for user and computer attributes**. Like files, user and computer objects can have attributes, and changes to these attributes can impact the user's ability to access files. Therefore, it can be valuable to track changes to user or computer attributes. User and computer objects are stored in AD DS; therefore, changes to their attributes can be audited. For more information, see DS Access .

- **Policy change staging**. Changes to central access policies can impact the access control decisions on all computers where the policies are enforced. A loose policy could grant more access than desired, and an overly restrictive policy could generate an excessive number of Help Desk calls. As a result, it can be extremely valuable to verify changes to a central access policy before enforcing the change. For that purpose, Windows Server 2012 introduces the concept of "staging." Staging enables users to verify their proposed policy changes before enforcing them. To use policy staging, proposed policies are deployed with the enforced policies, but staged policies do not actually grant or deny permissions. Instead, Windows Server 2012 logs an audit event (4818) any time the result of the access check that uses the staged policy is different from the result of an access check that uses the enforced policy.

Deploy Security Auditing with Central Audit Policies (Demonstration Steps)

In this scenario, you will audit access to files in the Finance Documents folder by using the Finance Policy that you created in Deploy a Central Access Policy (Demonstration Steps). If a user who is not authorized to access the folder attempts to access it, the activity is captured in the event viewer.

The following steps are required to test this scenario.

Task	Description
Configure global object access policy	In this step, you configure the global object access policy on the domain controller.
Update Group Policy settings	Sign in to the file server and apply the Group Policy update.
Verify that the global object access policy has been applied	View the relevant events in the event viewer. The events should include metadata for the country and document type.

Configure global object access policy

In this step, you configure the global object access policy in the domain controller.

To configure a global object access policy

1. Sign in to the domain controller DC1 as contoso\administrator with the password **pass@word1**.
2. In Server Manager, point to **Tools**, and then click **Group Policy Management**.
3. In the console tree, double-click **Domains**, double-click **contoso.com**, click **Contoso**, and then double-click **File Servers**.
4. Right-click **FlexibleAccessGPO**, and click **Edit**.
5. Double-click **Computer Configuration**, double-click **Policies**, and then double-click **Windows Settings**.
6. Double-click **Security Settings**, double-click **Advanced Audit Policy Configuration**, and then double-click **Audit Policies**.
7. Double-click **Object Access**, and then double-click **Audit File System**.
8. Select the **Configure the following events** check box, select the **Success** and **Failure** check boxes, and then click **OK**.
9. In the navigation pane, double-click **Global Object Access Auditing**, and then double-click **File system**.
10. Select the **Define this policy setting** check box, and click **Configure**.
11. In the **Advanced Security Settings for Global File SACL** box, click **Add**, then click **Select a principal**, type **Everyone**, and then click **OK**.
12. In the **Auditing Entry for Global File SACL** box, select **Full control** in the **Permissions** box.
13. In the **Add a condition:** section, click **Add a condition** and in the drop-down lists select [**Resource**] [**Department**] [**Any of**] [**Value**] [**Finance**].
14. Click **OK** three times to complete the configuration of the global object access audit policy setting.
15. In the navigation pane, click **Object Access**, and in the results pane, double-click **Audit Handle Manipulation**. Click **Configure the following audit events**, **Success**, and **Failure**, click **OK**, and then close the flexible access GPO.

Update Group Policy settings

In this step, you update the Group Policy settings after you have created the audit policy.

To update Group Policy settings

1. Sign in to the file server, FILE1 as contoso\Administrator, with the password **pass@word1**.
2. Press the Windows key+R, then type **cmd** to open a Command Prompt window.

   Note
   If the **User Account Control** dialog box appears, confirm that the action it

displays is what you want, and then click **Yes**.

3. Type **gpupdate /force** and then press ENTER.

Verify that the global object access policy has been applied

After the Group Policy settings have been applied, you can verify that the audit policy settings were applied correctly.

To verify that the global object access policy has been applied

1. Sign in to client computer, CLIENT1 as Contoso\MReid. Browse to the folder \\FILE1\Finance Documents, and modify Word Document 2.
2. Sign in to the file server, FILE1 as contoso\administrator. Open Event Viewer, browse to **Windows Logs**, select **Security**, and confirm that your activities resulted in audit events **4656** and **4663** (even though you did not set explicit auditing SACLs on the files or folders that you created, modified, and deleted).

Important

A new logon event is generated on the computer where the resource is located, on behalf of the user for whom effective access is being checked. When analyzing security audit logs for user sign-in activity, to differentiate between logon events that are generated because of effective access and those generated because of an interactive network user sign in, the Impersonation Level information is included. When the logon event is generated because of effective access, the Impersonation Level will be Identity. A network interactive user sign in typically generates a logon event with the Impersonation Level = Impersonation or Delegation.

Scenario: Access-Denied Assistance

Users will get an access-denied message when they try to access shared files and folders on a file server for which they do not have permissions. Administrators often do not have the appropriate context to troubleshoot the access issue, which makes it hard to resolve the issue.

Scenario description

Access-denied assistance is a new feature in Windows Server 2012, which provides the following ways to troubleshoot issues that are related to access to files and folders:

- **Self-assistance.** If a user can determine the issue and remediate the problem so that they can get the requested access, the impact to the business is low, and no special exceptions are needed in the central access policy. Access-denied assistance provides an access-denied message that file server administrators can customize with information specific to their organizations. For example, an administrator could set the message so that users can request access from a data owner without involving the file server administrator.
- **Assistance by the data owner.** You can define a distribution list for shared folders, and configure it so that the folder owner receives an email notification when a user needs access. If the data owner does not know how to help the user get access, the owner can forward this information to the file server administrator.
- **Assistance by the file server administrator.** This type of assistance is available when the user cannot fix an issue and the data owner cannot help. Windows Server 2012 provides a user interface where file server administrators can view the effective permissions for a user on a file or folder so that it is easier to troubleshoot access issues.

Access-denied assistance in Windows Server 2012 provides file server administrators the relevant access details so that they can determine the issue and appropriate tools so that they can make configuration changes to satisfy the access request. For example, a user might follow this process to access a file that they currently do not have access to:

- The user attempts to read a file in the \\financeshares shared folder, but the server displays an access-denied message.
- Windows Server 2012 displays the access-denied assistance information to the user with an option to request assistance.
- If the user requests access to the resource, the server sends an email with the access request information to the folder owner.

You can find planning information for configuring access-denied assistance in Plan for Access-Denied Assistance.

You can find steps about configuring access-denied assistance in Deploy Access-Denied Assistance (Demonstration Steps).

In this scenario

This scenario is part of the Dynamic Access Control scenario. For additional information about Dynamic Access Control, see:

- Dynamic Access Control: Scenario Overview

Practical applications

Access-denied assistance in Windows Server 2012 contributes to Dynamic Access Control by giving users the ability to request access to shared files and folders directly from an access-denied message.

Features included in this scenario

The following table lists the features that are part of this scenario and describes how they support it.

Feature	How it supports this scenario
File Server Resource Manager Overview	Access-denied assistance can be configured by using the File Server Resource Manager console on the file server.
File and Storage Services Overview	File Server Resource Manager is a File and Storage Services role service, and it is comprised of a set of features that can be used to administer the file servers on your network.

Plan for Access-Denied Assistance

There are a few considerations and decisions that should be made before you deploy access-denied assistance.

Use the following table to plan your access-denied assistance deployment in your organization.

Task	Description
1.1 Determine the access-denied assistance model	Determine whether your organization should use an email model or a Web services model for access-denied assistance.
1.2. Determine who should handle access requests	You can assign each file share an owner distribution list that will receive access requests.
1.3. Customize the access-denied assistance message	The access-denied assistance message should be customized for your organization. The included message is only a sample.
1.4. Plan for exceptions	Exceptions happen when a user account needs access to a specific file share but they do not

Task	Description
	need access to everything that the security group has.
1.5. Determine how access-denied assistance is deployed	Access-denied assistance can be configured at the file server level or at the file share level.

1.1 Determine the access-denied assistance model

There are two ways that you can configure access-denied assistance in your organization:

- **Email model** In an email model, if a user is denied access, a customized error message is shown with a button to request assistance. When the user clicks the **Request Assistance** button, an email is sent to the folder owner with the specified information.
- **Web services model** The Web services model is similar to the email model. Instead of the request assistance button being shown, a link is included in the access-denied assistance message that directs the user to request access through a self-service portal, such as Forefront Identity Manager.

The model that you choose is dependent on your organization.

1.2. Determine who should handle access requests

When using the email model each of the file shares, you can determine whether access requests to each file share will be received by the administrator, a distribution list that represents the file share owners, or both.

The owner distribution list is configured by using the **SMB Share – Advanced** file share profile in the New Share Wizard in Server Manager.

You can also use the File Server Resource Manager console to configure the owner distribution list by editing the management properties of the classification properties.

1.3. Customize the access-denied assistance message

Windows Server 2012 contains a sample message when you enable access-denied assistance. You should customize this message to meet the needs of your organization. One thing to consider including in the message is a link to your Intranet or help desk location.

You can also provide a specific access-denied assistance message per file share. This message will replace the global message when a user tries to access files within file share. For more

information on how to configure a separate access-denied assistance message for a file share, see Deploy Access-Denied Assistance (Demonstration Steps).

1.4. Plan for exceptions

How to deal with exceptions is an important consideration to plan for before you deploy access-denied assistance. Exceptions can happen if a user account needs access to a file share.

We recommend that the user account should not be added to any of the security groups that have access as part of the user's role. Instead, you should create another security group for exceptions that contains those user accounts and grant access to the appropriate file share so that you can monitor this security group separately and enforce rules, such as expiring membership.

1.5. Determine how access-denied assistance is deployed

Access-denied assistance can be configured on a per-file server or per-share basis. By configuring access-denied assistance at the file share level, you can customize the message to include specific information about the file share itself. For example, you could specify the exception security group for that share in the message so the user would know which group in which they should request access. Another example is to specify a specific owner distribution list for the folder that represents the file share.

Note

Some settings are global for the server. Enabling or disabling access-denied assistance is done on a server basis and the **Request Assistance** button is configured the file server level, so if you configure the file server to show the **Request Assistance** button, you cannot disable it on specific file shares.

For more information on configuring access-denied assistance at both a file share level and at a server level, see Deploy Access-Denied Assistance (Demonstration Steps).

Deploy Access-Denied Assistance (Demonstration Steps)

This topic explains how to configure access-denied assistance, and verify that it is working properly.

In this document

- Step 1: Configure access-denied assistance
- Step 2: Configure the email notification settings
- Step 3: Verify that access-denied assistance is configured correctly

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

Step 1: Configure access-denied assistance

You can configure access-denied assistance within a domain by using Group Policy, or you can configure the assistance individually on each file server by using the File Server Resource Manager console. You can also change the access-denied message for a specific shared folder on a file server.

You can configure access-denied assistance for the domain by using Group Policy as follows:

Do this step using Windows PowerShell

To configure access-denied assistance by using Group Policy

1. Open Group Policy Management. In Server Manager, click **Tools**, and then click **Group Policy Management**.
2. Right-click the appropriate Group Policy, and then click **Edit**.
3. Click **Computer Configuration**, click **Policies**, click **Administrative Templates**, click **System**, and then click **Access-Denied Assistance**.
4. Right-click **Customize message for Access Denied errors**, and then click **Edit**.
5. Select the **Enabled** option.
6. Configure the following options:
   a. In the **Display the following message to users who are denied access** box, type a message that users will see when they are denied access to a file or folder.

      You can add macros to the message that will insert customized text. The macros include:

      - **[Original File Path]** The original file path that was accessed by the user.
      - **[Original File Path Folder]** The parent folder of the original file path that was accessed by the user.

- **[Admin Email]** The administrator email recipient list.
- **[Data Owner Email]** The data owner email recipient list.

b. Select the **Enable users to request assistance** check box.

c. Leave the remaining default settings.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName AllowEmailRequests
–Type DWORD –value 1

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName GenerateLog –Type
DWORD –value 1

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName
IncludeDeviceClaims –Type DWORD –value 1

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName IncludeUserClaims
–Type DWORD –value 1

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName PutAdminOnTo –Type
DWORD –value 1

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName PutDataOwnerOnTo –
Type DWORD –value 1

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName ErrorMessage –Type
MultiString –value “Type the text that the user will see in the error message dialog
box.”

Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\Software\Policies\Microsoft\Windows\ADR\AccessDenied” –ValueName Enabled –Type
DWORD –value 1
```

Alternatively, you can configure access-denied assistance individually on each file server by using the File Server Resource Manager console.

Do this step using Windows PowerShell

To configure access-denied assistance by using File Server Resource Manager

1. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
2. Right-click **File Server Resource Manager (Local)**, and then click **Configure Options**.
3. Click the **Access-Denied Assistance** tab.
4. Select the **Enable access-denied assistance** check box.
5. In the **Display the following message to users who are denied access to a folder or file** box, type a message that users will see when they are denied access to a file or folder.

   You can add macros to the message that will insert customized text. The macros include:

   - **[Original File Path]** The original file path that was accessed by the user.
   - **[Original File Path Folder]** The parent folder of the original file path that was accessed by the user.
   - **[Admin Email]** The administrator email recipient list.
   - **[Data Owner Email]** The data owner email recipient list.
6. Click **Configure email requests**, select the **Enable users to request assistance** check box, and then click **OK**.
7. Click **Preview** if you want to see how the error message will look to the user.
8. Click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-FSRMAdrSetting -Event "AccessDenied" –DisplayMessage “Type the text that the user will see in the error message dialog box.” -Enabled:$true -AllowRequests:$true
```

After you configure the access-denied assistance, you must enable it for all file types by using Group Policy.

Do this step using Windows PowerShell

To configure access-denied assistance for all file types by using Group Policy

1. Open Group Policy Management. In Server Manager, click **Tools**, and then click **Group Policy Management**.
2. Right-click the appropriate Group Policy, and then click **Edit**.
3. Click **Computer Configuration**, click **Policies**, click **Administrative Templates**, click **System**, and then click **Access-Denied Assistance**.
4. Right-click **Enable access-denied assistance on client for all file types**, and then click **Edit**.
5. Click **Enabled**, and then click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-GPRegistryValue –Name “Name of GPO” –key
“HKLM\SOFTWARE\Policies\Microsoft\Windows\Explorer” –ValueName
EnableShellExecuteFileStreamCheck –Type DWORD –value 1
```

You can also specify a separate access-denied message for each shared folder on a file server by using the File Server Resource Manager console.

Do this step using Windows PowerShell

To specify a separate access-denied message for a shared folder by using File Server Resource Manager

1. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
2. Expand **File Server Resource Manager (Local)**, and then click **Classification Management**.
3. Right-click **Classification Properties**, and then click **Set Folder Management Properties**.
4. In the **Property** box, click **Access-Denied Assistance Message**, and then click **Add**.
5. Click **Browse**, and then choose the folder that should have the custom access-denied message.
6. In the **Value** box, type the message that should be presented to the users when they cannot access a resource within that folder.

   You can add macros to the message that will insert customized text. The macros include:

   - **[Original File Path]** The original file path that was accessed by the user.
   - **[Original File Path Folder]** The parent folder of the original file path that was accessed by the user.
   - **[Admin Email]** The administrator email recipient list.
   - **[Data Owner Email]** The data owner email recipient list.
7. Click **OK**, and then click **Close**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-FSRMMgmtProperty -Namespace "folder path" -Name "AccessDeniedMessage_MS" -Value “Type
the text that the user will see in the error message dialog box.”
```

Step 2: Configure the email notification settings

You must configure the email notification settings on each file server that will send the access-denied assistance messages.

Do this step using Windows PowerShell

1. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
2. Right-click **File Server Resource Manager (Local)**, and then click **Configure Options**.
3. Click the **Email Notifications** tab.
4. Configure the following settings:
   - In the **SMTP server name or IP address** box, type the name of IP address of the SMTP server in your organization.
   - In the **Default administrator recipients** and **Default "From" e-mail address** boxes, type the email address of the file server administrator.
5. Click **Send Test E-mail** to ensure that the email notifications are configured correctly.
6. Click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
set-FSRMSetting -SMTPServer "server1" -AdminEmailAddress "fileadmin@contoso.com" -
FromEmailAddress "fileadmin@contoso.com"
```

Step 3: Verify that access-denied assistance is configured correctly

You can verify that the access-denied assistance is configured correctly by having a user who is running Windows 8 try to access a share or a file in that share that they do not have access to. When the access-denied message appears, the user should see a **Request Assistance** button. After clicking the Request Assistance button, the user can specify a reason for access and then send an email to the folder owner or file server administrator. The folder owner or file server administrator can verify for you that the email arrived and contains the appropriate details.

Important

If you want to verify access-denied assistance by having a user who is running Windows Server 2012, you must install the Desktop Experience before connecting to the file share.

- Plan for Access-Denied Assistance
- Dynamic Access Control: Scenario Overview

Scenario: Classification-Based Encryption for Office Documents

Protection of sensitive information is mainly about mitigating risk for the organization. Various compliance regulations, such as the Health Insurance Portability and Accountability Act (HIPAA) and Payment Card Industry Data Security Standard (PCI-DSS), dictate encryption of information, and there are numerous business reasons to encrypt sensitive business information. However, encrypting information is expensive, and it might impair business productivity. Thus, organizations tend to have different approaches and priorities for encrypting their information.

Scenario description

Windows Server 2012 provides the ability to automatically encrypt sensitive Microsoft Office files, based on their classification. This is done through file management tasks that invoke Active Directory Rights Management Services (AD RMS) protection for sensitive documents a few seconds after the file is identified as being a sensitive file on the file server. This is facilitated by continuous file management tasks on the file server.

AD RMS encryption provides another layer of protection for files. Even if a person with access to a sensitive file inadvertently sends that file through email, the file is protected by the AD RMS encryption. Users who want to access the file must first authenticate themselves to an AD RMS server to receive the decryption key. The following figure shows this process.

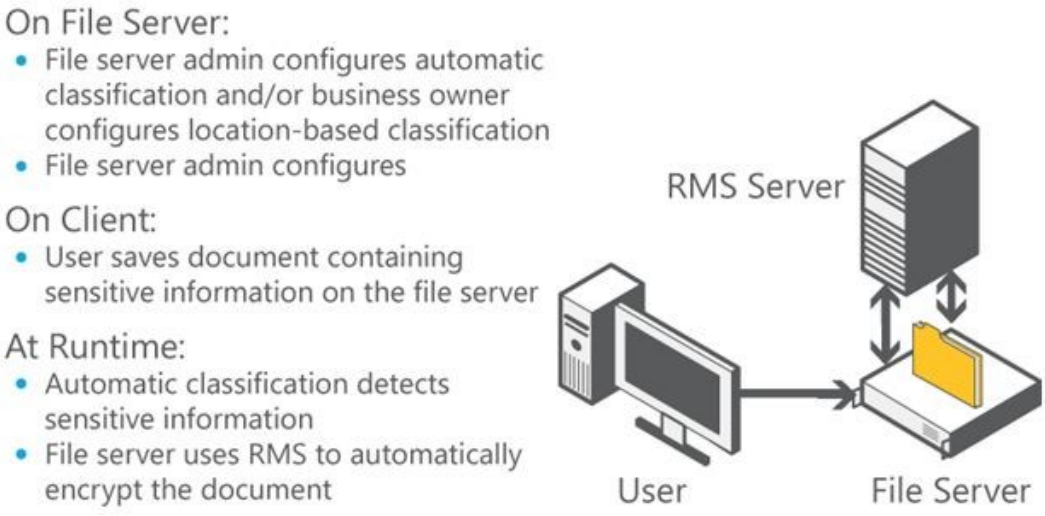

Figure 6 Classification-based RMS protection

Support for non-Microsoft file formats is available through non-Microsoft vendors. After a file has been protected by AD RMS encryption, data management features such as search- or content-based classification are no longer available for that file.

In this scenario

Following is the guidance that is available for this scenario:

- Planning Considerations for Encryption of Office Documents
- Deploy Encryption of Office Files (Demonstration Steps)
- Dynamic Access Control: Scenario Overview

Roles and features included in this scenario

The following table lists the roles and features that are part of this scenario and describes how they support it.

Role/feature	How it supports this scenario
Active Directory Domain Services role (AD DS)	AD DS provides a distributed database that stores and manages information about network resources and application-specific data from directory-enabled applications. In this scenario, AD DS in Windows Server 2012 introduces a claims-based authorization platform that enables the creation of user claims and device

Role/feature	How it supports this scenario
	claims, compound identity (user plus device claims), a new central access policies model, and the use of file-classification information in authorization decisions.
File and Storage Services role File Server Resource Manager	File and Storage Services provides technologies to help you set up and manage one or more file servers that provide central locations on your network where you can store files and share them with users. If your network users need access to the same files and applications, or if centralized backup and file management are important to your organization, you should set up one or more computers as a file server by adding the File and Storage Services role and the appropriate role services to the computers. In this scenario, file server administrators can configure file management tasks that invoke AD RMS protection for sensitive documents a few seconds after the file is identified as being a sensitive file on the file server (continuous file management tasks on the file server).
Active Directory Rights Management Services (AD RMS) role	AD RMS enables individuals and administrators (through Information Rights Management (IRM) policies) to specify access permissions to documents, workbooks, and presentations. This helps prevent sensitive information from being printed, forwarded, or copied by unauthorized people. After permission for a file has been restricted by using IRM, the access and usage restrictions are enforced no matter where the information is, because the permission to a file is stored in the document file itself. In this scenario, AD RMS encryption provides another layer of protection for files. Even if a person with access to a sensitive file inadvertently sends that file through email, the file is protected by the AD RMS encryption. Users who want to access the file must first authenticate themselves to an AD RMS server

Role/feature	How it supports this scenario
	to receive the decryption key.

Planning Considerations for Encryption of Office Documents

Active Directory Rights Management Services (AD RMS) is an information protection technology that can be used with dynamic access control to protect files as they are flexibly exchanged within an organization or across organizational boundaries. AD RMS works with Microsoft Office to help safeguard documents by enabling information rights management (IRM) features when you create documents using enabled applications such as Microsoft Word and Microsoft Outlook.

By using AD RMS to support the IRM feature capabilities within Microsoft Office, you can create documents or email messages and protect them from unauthorized use as they are flexibly shared in digital form. When assigning rights, content owners can define exactly how a recipient can use the information; including such rights as the ability to open, modify, print, or forward the information.

Note
AD RMS can be implemented to provide a comprehensive information-protection platform in complex business environments. Additionally, it can be effectively implemented to protect information shared among multiple organizations. For more on planning deployment scenarios around AD RMS, see AD RMS Architecture Design and Secure Collaboration Scenarios(http://go.microsoft.com/fwlink/?LinkId=256399).

This topic provides guidance around the following additional considerations that should be looked at when you are using AD RMS to protect and encrypt Office documents that you will provide limited access to by sharing them using dynamic access control. (For more about how dynamic access control works, see Dynamic Access Control: Scenario Overview.)

- Determining files to automatically encrypt
- Determining the rights policy template to use when encrypting files
- Multi-machine considerations

Determining files to automatically encrypt

In determining which files or folders to automatically encrypt using AD RMS technology, there are two aspects to consider. First, you should determine what types of files need to be encrypted. For example, do you have files containing confidential information or personal information?

Next, you should determine which resource properties are useful ways to describe those types of files. To get started, try to use the predefined resource properties whenever possible. Typically, this will mean selecting the most appropriate resource property from the list of resource

properties that are either built-in or user-defined using Active Directory Administrative Center. For example, the following table provides suggestions for some of the exact built-in resource properties you might choose to use when identifying files to be marked for encryption and rights protection.

Resource Property	Description
PII	The Personal Identifying Information (PII) resource property can be used to identify files that have PII within them to ensure those files are protected at the appropriate assigned level of sensitivity. For example,
Compliancy	The Compliancy property for confidentiality purposes according HIPAA guidelines in an organization that provides health care services.
Project	This resource property can be used to set a list of name values for which the name of a special project in your organization could be applied to all of its related files. This could identify project files for the purposes of them having encryption and protection applied to them, ensuring that only project team members have access to open and view these files.

In addition to the above resource properties, you might choose to have other custom resource properties defined in your deployment that apply the following criterion:

- **Based on file location**. You might create a new resource property definition called "Location" and then set list of supported values for it to the names of specific sites or locations within your enterprise or organization. You could then assign the values to this resource property for each of the files by their location. This might be a good strategy to implement if you have a secure location that requires all documents within it to be encrypted and protected.
- **Based on file contents**. Another way to create a resource property to help protect content based on identifying the type of content it is. For example, if you only need to protect files or documents that have sensitive financial or payroll information, you might choose to use "Financial" or "Payroll" as supported values for a "Content" resource property and use that property to identify and tag files that need to be encrypted and protected.
- **Based on manual classification**. Another possible way to identify files for classification is to manually classify them. Manual classification gives users and content owners the ability to classify their files and folders by using the properties sheet of that file or folder. For example, you can classify folders so that any file added to the folder will inherit the classifications of the parent folder. For more information, see Working with File Classification.

Determining the rights policy template to use when encrypting files

Rights policy templates are used in AD RMS to control the rights that a user or group has on a particular piece of rights-protected content. When you are deciding upon which rights policy template to use when encrypting files in your organization, it's helpful to consider the purpose and scope of how you are planning to protect content.

For example, you might consider using a rights policy template for the purpose of protecting PII content that would be generated by the finance or payroll department within your organization. In this case you could name the template "Finance" and select the following configuration user and rights settings when creating the template in the AD RMS console.

- Configure an Active Directory group to be assigned use of the template, one that contains only the regular staff employees who work within the finance or payroll department. Note that this group will also need to be configured for an email name for AD RMS to use in identifying it such as "finance@contoso.com" or "payroll@contoso.com".
- Select **View** and **View Rights** to limit the department employees in their ability to modify payroll or other financial details for documents.

Similar template configurations might also be done to protect content considered to be High Business Impact (HBI) information by having a "Company Confidential" template that enforces similar view-only rights and limited to all full-time employees only.

Another way of determining a rights policy template to use would be to apply scope as the determining factor. One way to do this would be to reserve the use of separate network mapped drives or volumes for each department so they can be used by workers within the department to store their documents. In this scenario, you might have templates that are specific to each department and ensuring that they are only available to be applied to files on that department's mapped drive or volume.

For example, the finance department might have their work files managed using a template for volume (drive) F and the engineering department might use volume G for storing their protected work files. File management has been configured so that workers in each department do not have access to the other department's volume. This will be useful if you if you need to create more than one file management task to manage protection for multiple departments and rights policy templates.

Note

There should be only a 1:1 relationship between templates and file management tasks. In general, you should try to use only a single file management task and rights policy template throughout your organization to schedule and manage template usage. If you do use more than one template and file management task as suggested here, be sure to take the suggested precautions and manage separate scope well so that tasks and volumes where files are managed are not able to be assigned protection using more than a single template to avoid rights conflicts or collisions.

For more information on working with AD RMS rights policy templates, see the following additional resources:

- Configuring Rights Policy Templates
- Working with File Management Tasks
- Creating a New Rights Policy Template (Using Windows PowerShell)
- AD RMS Rights Policy Templates Deployment Step-by-Step Guide
- AD RMS Rights Policy Template Considerations
- AD RMS Rights Policy Templates Best Practices

Multi-machine considerations

In working to plan encryption for the files you use in your organization, there are a number of aspects to consider in preparing for multi-machine deployment. To begin with, there is no easy way to push file management tasks and classification rules out to multiple computers. Therefore, it is common practice for those working with dynamic access control to do new configuration by transferring settings from one computer to another manually, although there are some tools that can assist in this process.

Dynamic scope using the FolderUsage property

For each file management task and classification rule, you can use a management property in a way that allows for dynamic scoping in contrast to a statically specified scope. In static scoping, a file management task, a classification rule or a report is defined using specific folder shares, paths or volumes that are specific to the computer where the rule was made. Since each computer has a different share / folder / volume structure, a statically scoped rule is likely not work if copied to other computers.

Dynamic scoping allows a task, rule or report to be defined in such a way that it can be correct calculated on any computer where the task, rule or report is placed. A dynamically scoped rule might use a management property to help calculate and apply the rule to folders by looking at how they are marked for usage. For example, you might have two servers, Server1 and Server2. On Server1, D:\share might contain files with user data and on Server2, E:\share is the share used for the same purpose. To apply dynamic scope, you could then specify a file management task that applies to all folders marked as containing FolderUsage="User Data". By doing so, the rule would work correctly on both servers with no modification.

Note

For dynamic scope, always use the FolderUsage property definition, one of three special management property definitions that are built in to the File Services infrastructure.

Setting management property values

While "User Data" (as was described in the previous section) is one possible value for the FolderUsage management property that could be applied, others include "Collaboration Data" or "Application Data" and these classifications can be modified, extended or deleted as needed. If you do want to modify a management property such as FolderUsage, the following are all possible ways to do so:

1. You can set the management property in the New Share Wizard.
2. In the File Services Resource Manager (FSRM) console, in the treeview on the left, select **Classification Properties**, and then select **Set Management Properties** in the task pane on the right.
3. Using Windows PowerShell, you can use the **Get-FSRMMgmtProperty** and **Set-FSRMMgmtProperty** cmdlets to view status on management properties or configure them.

Moving configurations between computers

Once you have set or updated management properties on a single computer you will want to be able to move your configuration changes to others computers. The following are three possible options for doing so:

- **Write a script that configures File Classification Infrastructure (FCI).**

  To alter the FCI configuration on multiple computers, you can write a COM-based script that uses the FCI API to create new file classifications and to store new properties. You can then create applications or scripts that can be initiated by file management tasks in File Services Resource Manager (FSRM) or you can also use Group Policy to launch completed scripts. For more information on the FCI API, see IFsrmPipelineModuleImplementation Interface
- **Use Windows PowerShell remoting to use the File Services Resource Manager (FSRM) cmdlets to configure computers.**

  Windows PowerShell provides another scripting platform you can leverage to perform configuration updates. For more information on using Windows PowerShell to create FCI scripts, see Using Windows PowerShell Script for File Classification.
- **Use the Data Classification Toolkit to export and then import configurations.**

  The Data Classification Toolkit provides another option for exporting and importing FCI configurations. It was designed to help enable an organization to identify, classify, and protect data on its file servers and it provides out-of-the-box classification and rule examples that can help organizations build and deploy their policies to protect critical information in a cost-effective manner. For more information, see Data Classification Toolkit.

Deploy Encryption of Office Files (Demonstration Steps)

Contoso's Finance Department has a number of file servers that store their documents. These documents can be general documentation or they can have a high-business impact (HBI). For example, any document that contains confidential information is deemed, by Contoso, to have a high-business impact. Contoso wants to ensure that all their documentation has a minimum amount of protection and that their HBI documentation is restricted to the appropriate people. To accomplish this, Contoso is exploring using the File Classification Infrastructure (FCI) and AD RMS that is available in Windows Server 2012. By using FCI, Contoso will classify all of the documents on their file server, based on the content, and then use AD RMS to apply the appropriate rights policy.

In this scenario, you'll perform the following steps:

Task	Description
Step 1: Enable resource properties	Enable the **Impact** and **Personally Identifiable Information** resource properties.
Step 2: Create classification rules	Create the following classification rules: **HBI Classification Rule** and **PII Classification Rule**.
Step 3: Use file management tasks to automatically protect documents with AD RMS	Create a file management task that automatically used AD RMS to protect documents with high personally identifiable information (PII). Only members of the FinanceAdmin group will have access to documents that contain high PII.
Step 4: View the results	Examine the classification of documents and observe how they change as you change the content in the document. Also verify how the document gets protected by AD RMS.
Step 5: Verify protection with AD RMS	Verify that the document is protected with AD RMS.

Step 1: Enable resource properties

To enable resource properties

1. In Hyper-V Manager, connect to server ID_AD_DC1. Sign in to the server by using Contoso\Administrator with the password **pass@word1**.
2. Open Active Directory Administrative Center, and click **Tree View**.
3. Expand **DYNAMIC ACCESS CONTROL**, and select **Resource Properties**.
4. Scroll down to the **Impact** property in the **Display name** column. Right-click **Impact**, and then click **Enable**.
5. Scroll down to the **Personally Identifiable Information** property in the **Display name** column. Right-click **Personally Identifiable Information**, and then click **Enable**.
6. To publish the resource properties in the **Global Resource List**, in the left pane, click **Resource Property Lists**, and then double-click **Global Resource Property List**.
7. Click **Add**, and then scroll down to and click **Impact** to add it to the list. Do the same for **Personally Identifiable Information**. Click **OK** twice to finish.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-ADResourceProperty -Enabled:$true -Identity:"CN=Impact_MS,CN=Resource
Properties,CN=Claims Configuration,CN=Services,CN=Configuration,DC=contoso,DC=com"
Set-ADResourceProperty -Enabled:$true -Identity:"CN=PII_MS,CN=Resource
Properties,CN=Claims Configuration,CN=Services,CN=Configuration,DC=contoso,DC=com"
```

Step 2: Create classification rules

This step explains how to create the **High Impact** classification rule. This rule will search the content of documents and if the string “Contoso Confidential” is found, it will classify this document as having high-business impact. This classification will override any previously assigned classification of low-business impact.

You will also create a **High PII** rule. This rule searches the content of documents, and if a Social Security number is found, it classifies the document as having high PII.

To create the high-impact classification rule

1. In Hyper-V Manager, connect to server ID_AD_FILE1. Sign in to the server by using Contoso\Administrator with the password **pass@word1**.
2. You need to refresh the Global Resource Properties from Active Directory. Open Windows PowerShell and type: `Update-FSRMClassificationPropertyDefinition`, and then press ENTER. Close Windows PowerShell.
3. Open File Server Resource Manager. To open File Server Resource Manager, click **Start**, type **file server resource manager**, and then click **File Server Resource Manager**.
4. In the left pane of File Server Resource Manager, expand **Classification Management**,

and then select **Classification Rules**.

5. In the **Actions** pane, click **Configure Classification Schedule**. On the **Automatic Classification** tab, select **Enable fixed schedule**, select a **Day of the week**, and then select the **Allow continuous classification for new files** check box. Click **OK**.
6. In the **Actions** pane, click **Create Classification Rule**. This opens the **Create Classification Rule** dialog box.
7. In the **Rule name** box, type **High Business Impact**.
8. In the **Description** box, type **Determines if the document has a high business impact based on the presence of the string "Contoso Confidential"**
9. On the **Scope** tab, click **Set Folder Management Properties**, select **Folder Usage**, click **Add**, then click **Browse**, browse to D:\Finance Documents as the path, click **OK**, and then choose a property value named **Group Files** and click **Close**. Once management properties are set, on the **Rule Scope** tab select **Group Files**.
10. Click the **Classification** tab. Under **Choose a method to assign the property to files**, select **Content Classifier** from the drop-down list.
11. Under **Choose a property to assign to files**, select **Impact** from the drop-down list.
12. Under **Specify a value**, select **High** from the drop-down list.
13. Click **Configure** under **Parameters**. In the **Classification Parameters** dialog box, in the **Expression Type** list, select **String**. In the **Expression** box, type: **Contoso Confidential**, and then click **OK**.
14. Click the **Evaluation Type** tab. Click **Re-evaluate existing property values**, click **Overwrite** the existing value, and then click **OK** to finish.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Update-FSRMClassificationPropertyDefinition

$date = Get-Date

$AutomaticClassificationScheduledTask = New-FsrmScheduledTask -Time $date -Weekly @(3, 2, 4, 5,1,6,0) -RunDuration 0;

Set-FsrmClassification -Continuous -schedule $AutomaticClassificationScheduledTask

New-FSRMClassificationRule -Name "High Business Impact" -Property "Impact_MS" -Description "Determines if the document has a high business impact based on the presence of the string 'Contoso Confidential'" -PropertyValue "3000" -Namespace @("D:\Finance Documents") -ClassificationMechanism "Content Classifier" -Parameters @("StringEx=Min=1;Expr=Contoso Confidential") -ReevaluateProperty Overwrite
```

To create the high-PII classification rule

1. In Hyper-V Manager, connect to server ID_AD_FILE1. Sign in to the server by using Contoso\Administrator with the password **pass@word1**.

2. On the desktop, open the folder named **Regular Expressions**, and then open the text document named **RegEx-SSN**. Highlight and copy the following regular expression string: **^(?!000)([0-7]\d{2}|7([0-7]\d|7[012]))([-]?)(?!00)\d\d\3(?!0000)\d{4}$**. This string will be used later in this step so keep it on your clipboard.
3. Open File Server Resource Manager. To open File Server Resource Manager, click **Start**, type **file server resource manager**, and then click **File Server Resource Manager**.
4. In the left pane of File Server Resource Manager, expand **Classification Management**, and then select **Classification Rules**.
5. In the **Actions** pane, click **Configure Classification Schedule**. On the **Automatic Classification** tab, select **Enable fixed schedule**, select a **Day of the week**, and then select the **Allow continuous classification for new files** check box. Click OK.
6. In the **Rule name** box, type **High PII**. In the **Description** box, type **Determines if the document has a high PII based on the presence of a Social Security Number.**
7. Click the **Scope** tab, select the **Group Files** check box.
8. Click the **Classification** tab. Under **Choose a method to assign the property to files**, select **Content Classifier** from the drop-down list.
9. Under **Choose a property to assign to files**, select **Personally Identifiable Information** from the drop-down list.
10. Under **Specify a value**, select **High** from the drop-down list.
11. Click **Configure** under **Parameters**.
    In the **Classification Parameters** window, in the **Expression Type** list, select **Regular Expression**. In the **Expression** box, paste the text from your clipboard: **^(?!000)([0-7]\d{2}|7([0-7]\d|7[012]))([-]?)(?!00)\d\d\3(?!0000)\d{4}$**, and then click **OK**.

    Note
    This expression will allow invalid Social Security numbers. This allows us to use fictitious Social Security numbers in the demonstration.
12. Click the **Evaluation Type** tab. Select **Re-evaluate existing property values**, **Overwrite** the existing value, and then click **OK** to finish.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
New-FSRMClassificationRule -Name "High PII" -Description "Determines if the document has a high PII based on the presence of a Social Security Number." -Property "PII_MS" -PropertyValue "5000" -Namespace @("D:\Finance Documents") -ClassificationMechanism "Content Classifier" -Parameters @("RegularExpressionEx=Min=1;Expr=^(?!000)([0-7]\d{2}|7([0-7]\d|7[012]))([ -]?)(?!00)\d\d\3(?!0000)\d{4}$") -ReevaluateProperty Overwrite
```

You should now have two classification rules:

- High Business Impact

- High PII

Step 3: Use file management tasks to automatically protect documents with AD RMS

Now that you've created rules to automatically classify documents based on content, the next step is to create a file management task that uses AD RMS to automatically protect certain documents based on their classification. In this step, you will create a file management task that automatically protects any documents with a high PII. Only members of the FinanceAdmin group will have access to documents that contain high PII.

To protect documents with AD RMS

1. In Hyper-V Manager, connect to server ID_AD_FILE1. Sign in to the server by using Contoso\Administrator with the password **pass@word1**.
2. Open File Server Resource Manager. To open File Server Resource Manager, click **Start**, type **file server resource manager**, and then click **File Server Resource Manager**.
3. In the left pane, select **File Management Tasks**. In the **Actions** pane, select **Create File Management Task**.
4. In the **Task name:** field, type **High PII**. In the **Description** field, type **Automatic RMS protection for high PII documents**.
5. Click the **Scope** tab, select the **Group Files** check box.
6. Click the **Action** tab. Under **Type**, select **RMS Encryption**. Click **Browse** to select a template, and then select the **Contoso Finance Admin Only** template.
7. Click the **Condition** tab, and then click **Add**. Under **Property**, select **Personally Identifiable Information**. Under **Operator**, select **Equal**. Under **Value**, select **High**. Click **OK**.
8. Click the **Schedule** tab. In the **Schedule** section, click **Weekly**, and then select **Sunday**. Running the task once-a-week will ensure that you catch any documents that may have been missed due to a service outage or other disruptive event.
9. In the **Continuous operation** section, select **Run task continuously on new files**, and then click **OK**. You should now have a file management task named High PII.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
$fmjRmsEncryption = New-FSRMFmjAction -Type 'Rms' -RmsTemplate 'Contoso Finance Admin Only'

$fmjCondition1 = New-FSRMFmjCondition -Property 'PII_MS' -Condition 'Equal' -Value '5000'

$date = get-date
```

```
$schedule = New-FsrmScheduledTask -Time $date -Weekly @('Sunday')
$fmj1=New-FSRMFileManagementJob -Name "High PII" -Description "Automatic RMS protection
for high PII documents" -Namespace @('D:\Finance Documents') -Action $fmjRmsEncryption -
Schedule $schedule -Continuous -Condition @($fmjCondition1)
```

Step 4: View the results

It's time to take a look at your new automatic classification and AD RMS protection rules in action. In this step you will examine the classification of documents and observe how they change as you change the content in the document.

To view the results

1. In Hyper-V Manager, connect to server ID_AD_FILE1. Sign in to the server by using Contoso\Administrator with the password **pass@word1**.
2. In Windows Explorer, navigate to D:\Finance Documents.
3. Right-click the Finance Memo document and click **Properties**.Click the **Classification** tab, and notice that the Impact property currently has no value. Click **Cancel**.
4. Right-click the **Request for Approval to Hire document**, and then select **Properties**.
5. Click the **Classification** tab, and notice that **the Personally Identifiable Information property** currently has no value. Click **Cancel**.
6. Switch to CLIENT1. Sign off any user who is signed in, and then sign in as Contoso\MReid with the password **pass@word1**.
7. From the Desktop, open the **Finance Documents** shared folder.
8. Open the **Finance Memo** document. Near the bottom of the document, you will see the word **Confidential**. Modify it to read: **Contoso Confidential**. Save the document and close it.
9. Open the **Request for Approval to Hire** document. In the **Social Security#:** section, type: 777-77-7777. Save the document and close it.

   Note
   You may need to wait 30 seconds for the classification to occur.
10. Switch back to ID_AD_FILE1. In Windows Explorer, navigate to D:\Finance Documents.
11. Right-click the Finance Memo document, and click **Properties**. Click the **Classification** tab. Notice that the **Impact** property is now set to **High**. Click **Cancel**.
12. Right-click the Request for Approval to Hire document and click **Properties**.
13. . Click the **Classification** tab. Notice that the **Personally Identifiable Information** property is now set to **High**. Click **Cancel**.

Step 5: Verify protection with AD RMS

To verify that the document is protected

1. Switch back to ID_AD_CLIENT1.
2. Open the **Request for approval to Hire** document.
3. Click **OK** to allow the document to connect to your AD RMS server.
4. You can now see that the document has been protected by AD RMS because it contains a Social Security number.

Scenario: Get Insight into Your Data by Using Classification

Reliance on data and storage resources has continued to grow in importance for most organizations. IT administrators face the growing challenge of overseeing larger and more complex storage infrastructures, while simultaneously being tasked with the responsibility to ensure that total cost-of-ownership is maintained at reasonable levels. Managing storage resources is not only about the volume or availability of data; it is also about enforcing company policies and knowing how storage is consumed to enable efficient utilization and compliance to mitigate risk. File Classification Infrastructure provides insight into your data by automating classification processes so that you can manage your data more effectively. The following classification methods are available with File Classification Infrastructure: manual, programmatic, and automatic. This topic focuses on the automatic file classification method.

Scenario description

File Classification Infrastructure uses classification rules to automatically scan files and classify them according to the contents of the file. Classification properties are defined centrally in Active Directory so that these definitions can be shared across file servers in the organization. You can create classification rules that scan files for a standard string or for a string that matches a pattern (regular expression). When a configured classification parameter is found in a file, that file is classified as configured in the classification rule. Some examples of classification rules include:

- Classify any file that contains the string “Contoso Confidential” as having high business impact
- Classify any file that contains at least 10 social security numbers as having personally identifiable information

When a file is classified, you can use a file management task to take action on any files that are classified a specific way. The actions in a file management task include protecting the rights

associated with the file, expiring the file, and running a custom action (such as posting information to a web service).

You can find planning information for configuring automatic file classification in Plan for Automatic File Classification.

You can find steps for how to automatically classify files in Deploy Automatic File Classification (Demonstration Steps).

In this scenario

This scenario is part of the Dynamic Access Control scenario. For additional information about Dynamic Access Control, see:

- Dynamic Access Control: Scenario Overview

Practical applications

File Classification Infrastructure in Windows Server 2012 contributes to Dynamic Access Control by enabling business data owners to easily classify and label data. The classification information that is stored in the central access policy allows you to define access policies for data classes that are critical to business.

Features included in this scenario

The following table lists the features that are part of this scenario and describes how they support it.

Feature	How it supports this scenario
File Server Resource Manager Overview	File Classification Infrastructure is a feature that is included in File Server Resource Manager.
File and Storage Services Overview	File Server Resource Manager is a feature that is included with the File Services server role.

Plan for Automatic File Classification

Before you deploy file classification across the file servers in your organization, you should identify the information that should be classified and identify the appropriate classification method.

Use the following table to plan your automatic file classification deployment in your organization.

Task	Description
1.1. Identify what information to classify in your environment	Inventory your existing data and decide what information needs to be classified before creating rules.
1.2. Identify how to classify files	Choose the appropriate classification method for the classification rule: manual, location-based, or content-based.
1.3. Considerations for multiple computers	Use the Data Classification Toolkit when possible to export the configuration from a baseline computer and import it on the file servers.

1.1. Identify what information to classify in your environment

You should start by doing an inventory on the existing data on all files in your organization. From there, you should list the classification requirements and use that list to figure out which file and folder should be classified. Be sure to ensure that you consider any regulations, such as HIPAA, while you are listing the classification requirements.

Before you create any new classification properties, ensure that a matching resource property does not already exist in Active Directory Domain Services. If one already exists, you should enable that resource property before creating a new one.

1.2. Identify how to classify files

When you identify the files that should be classified, you should include both new and existing files in your organization. There are three ways to classify files:

- **Manual** You can classify files manually by using the **Classification** tab of the properties sheet of the file.
- **Location-based** Location-based classification can be used by classifying folders manually using the **Classification** tab or by using the folder classifier in a classification rule.
- **Content-based** Content-based classification can be deployed by using the content classifier in a classification rule. The Data Classification Toolkit includes some built-in rules for determining personally identifiable information. More information on the Data Classification Toolkit can be found on the TechNet website.

If the folder and content classifiers do not fit the requirements of your organization, you can use the Windows PowerShell classifier or purchase a non-Microsoft classifier. The Windows PowerShell classifier allows you to write a Windows PowerShell script that returns true or false. If true, the file is classified according to the classification rule.

1.3. Considerations for multiple computers

There are several things to consider when you have more than one file server in your organization:

- The Data Classification Toolkit uses Windows PowerShell cmdlets to import and export classification rules. You should be this to export the configuration from a baseline computer and import to another computer to ensure that the configuration is the same.
- You should use dynamic name spaces when the source and destination servers use the same drive letters for the storage on the server. When you create a new file share by using Server Manager, you can specify the name space. For more information about dynamic name spaces, see What's New in File Server Resource Manager in Windows Server 2012.

Deploy Automatic File Classification (Demonstration Steps)

This topic explains how to enable resource properties in Active Directory, create classification rules on the file server, and then assign values to the resource properties for files on the file server. For this example, the following classification rules are created:

- A content classification rule that searches a set of files for the string “Contoso Confidential.” If the string is found in a file, the Impact resource property is set to High on the file.
- A content classification rule that searches a set of files for a regular expression that matches a social security number at least 10 times in one file. If the pattern is found, the file is classified as having personally identifiable information and the Personally Identifiable Information resource property is set to High.

In this document

- **Step 1: Create resource property definitions**
- **Step 2: Create a string content classification rule**
- **Step 3: Create a regular expression content classification rule**
- Step 4: Verify that the files are classified correctly

Note

This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

Step 1: Create resource property definitions

The Impact and Personally Identifiable Information resource properties are enabled so that File Classification Infrastructure can use these resource properties to tag the files that are scanned on a network shared folder.

Do this step using Windows PowerShell

To create resource property definitions

1. On the domain controller, sign in to the server as a member of the Domain Admins security group.
2. Open Active Directory Administrative Center. In Server Manager, click **Tools**, and then click **Active Directory Administrative Center**.
3. Expand **Dynamic Access Control**, and then click **Resource Properties**.
4. Right-click **Impact**, and then click **Enable**.
5. Right-click **Personally Identifiable Information**, and then click **Enable**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-ADResourceProperty -Enabled:$true -Identity:"CN=Impact_MS,CN=Resource
Properties,CN=Claims Configuration,CN=Services,CN=Configuration,DC=contoso,DC=com"
Set-ADResourceProperty -Enabled:$true -Identity:"CN=PII_MS,CN=Resource
Properties,CN=Claims Configuration,CN=Services,CN=Configuration,DC=contoso,DC=com"
```

Step 2: Create a string content classification rule

A string content classification rule scans a file for a specific string. If the string is found, the value of a resource property can be configured. In this example, we will scan each file on a network shared folder and look for the string "Contoso Confidential." If the string is found, the associated file is classified as having high business impact.

Do this step using Windows PowerShell

To create a string content classification rule

1. Log on to the file server as a member of the Administrators security group.
2. From the Windows PowerShell command prompt, type **Update-FsrmClassificationPropertyDefinition** and then press ENTER. This will synchronize the property definitions created on the domain controller to the file server.
3. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
4. Expand **Classification Management**, right-click **Classification Rules**, and then click

Configure Classification Schedule.

5. Select the **Enable fixed schedule** check box, select the **Allow continuous classification for new files** check box, choose a day of the week to run the classification, and then click **OK**.
6. Right-click **Classification Rules**, and then click **Create Classification Rule**.
7. On the **General** tab, in the **Rule name** box, type a rule name such as **Contoso Confidential**.
8. On the **Scope** tab, click **Add**, and choose the folders that should be included in this rule, such as D:\Finance Documents.

   Note
   You can also choose a dynamic name space for the scope. For more information about dynamic name spaces for classification rules, see What's New in File Server Resource Manager in Windows Server 2012.
9. On the **Classification** tab, configure the following:
   - In the **Choose a method to assign a property to files** box, ensure that **Content Classifier** is selected.
   - In the **Choose a property to assign to files** box, click **Impact**.
   - In the **Specify a value** box, click **High**.
10. Under the **Parameters** heading, click **Configure**.
11. In the **Expression Type** column, select **String**.
12. In the **Expression** column, type **Contoso Confidential**, and then click **OK**.
13. On the **Evaluation Type** tab, select the **Re-evaluate existing property values** check box, click **Overwrite the existing value**, and then click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
$date = Get-Date

$AutomaticClassificationScheduledTask = New-FsrmScheduledTask -Time $date -Weekly @(3, 2, 4, 5,1,6,0) -RunDuration 0;$AutomaticClassificationScheduledTask

Set-FsrmClassification -Continuous -schedule $AutomaticClassificationScheduledTask

New-FSRMClassificationRule -Name "Contoso Confidential" -Property "Impact_MS" -PropertyValue "3000" -Namespace @("D:\Finance Documents") -ClassificationMechanism "Content Classifier" -Parameters @("StringEx=Min=1;Expr=Contoso Confidential") -ReevaluateProperty Overwrite
```

Step 3: Create a regular expression content classification rule

A regular expression classification rule scans a file for a pattern that matches the regular expression. If a string that matches the regular expression is found, the value of a resource property can be configured. In this example, we will scan each file on a network shared folder and look for a string that matches the pattern of a social security number (XXX-XX-XXXX). If the pattern is found, the associated file is classified as having personally identifiable information.

Do this step using Windows PowerShell

To create a regular expression content classification rule

1. Sign in to the file server as a member of the Administrators security group.
2. From the Windows PowerShell command prompt, type **Update-FsrmClassificationPropertyDefinition**, and then press ENTER. This will synchronize the property definitions that are created on the domain controller to the file server.
3. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
4. Right-click **Classification Rules**, and then click **Create Classification Rule**.
5. On the **General** tab, in the **Rule name** box, type a name for the classification rule, such as PII Rule.
6. On the **Scope** tab, click **Add**, and then choose the folders that should be included in this rule, such as D:\Finance Documents.
7. On the **Classification** tab, configure the following:
   - In the **Choose a method to assign a property to files** box, ensure that **Content Classifier** is selected.
   - In the **Choose a property to assign to files** box, click **Personally Identifiable Information**.
   - In the **Specify a value** box, click **High**.
8. Under the **Parameters** heading, click **Configure**.
9. In the **Expression Type** column, select **Regular expression**.
10. In the **Expression** column, type **^(?!000)([0-7]\d{2}|7([0-7]\d|7[012]))([-]?)(?!00)\d\d\3(?!0000)\d{4}$**
11. In the **Minimum Occurrences** column, type **10**, and then click **OK**.
12. On the **Evaluation Type** tab, select the **Re-evaluate existing property values** check box, click **Overwrite the existing value**, and then click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
New-FSRMClassificationRule -Name "PII Rule" -Property "PII_MS" -PropertyValue "5000" -
Namespace @("D:\Finance Documents") -ClassificationMechanism "Content Classifier" -
Parameters @("RegularExpressionEx=Min=10;Expr=^(?!000)([0-7]\d{2}|7([0-7]\d|7[012]))([ -
]?)(?!00)\d\d\3(?!0000)\d{4}$") -ReevaluateProperty Overwrite
```

Step 4: Verify that the files are classified correctly

You can verify that the files are properly classified by viewing the properties of a file that was created in the folder specified in the classification rules.

To verify that the files are classified correctly

1. On the file server, run the classification rules by using File Server Resource Manager.
   a. Click **Classification Management**, right-click **Classification Rules**, and then click **Run Classification With All Rules Now**.
   b. Click the **Wait for classification to complete** option, and then click **OK**.
   c. Close the Automatic Classification Report.
   d. You can do this by using Windows PowerShell with the following command: **Start-FSRMClassification –RunDuration 0 -Confirm:$false**
2. Navigate to the folder that was specified in the classification rules, such as D:\Finance Documents.
3. Right-click a file in that folder, and then click **Properties**.
4. Click the **Classification** tab, and verify that the file is classified correctly.

Set up Manual File Classification

Users can manually classify files and folders using the File Classification Infrastructure in Windows Server 2012. Users can tag their data by the resource properties defined or enabled in the domain controller.

The following procedures provide manual file classification in your organization:

- Create/enable resource properties
- Set group policy settings to enable the manual classification UI on Windows 8 devices
- Classify the files and folders based on your resource properties

Create Resource Properties

The following procedure demonstrates how to create two resource properties: Country and Department.

To create and enable pre-created resource properties

1. In the left pane of Active Directory Administrative Center, click **Tree View**. Expand **Dynamic Access Control**, and then select **Resource Properties**.
2. Right-click **Resource Properties**, click **New**, and then click **Reference Resource Property**.

   Tip

   You can also choose a resource property from the **Tasks** pane. Click **New** and then click **Reference Resource Property**.
3. In **Select a claim type to share its suggested values list**, click **country**.
4. In the **Display name** field, type **country**, and then click **OK**.
5. Double-click the **Resource Properties** list, scroll down to the **Department** resource property. Right-click, and then click **Enable**. This will enable the built-in **Department** resource property.
6. In the **Resource Properties** list on the navigation pane of the Active Directory Administrative Center, you will now have two enabled resource properties:
   - Country
   - Department

Set Group Policy Settings for Manual File Classification

You need to set the following two group policy settings in order to enable the manual classification UI on Windows 8 devices:

- **File Classification Infrastructure: Display Classification tab in File Explorer**: This setting controls the display of the classification tab in the Properties tab of File Explorer.
- **File Classification Infrastructure: Specify classification properties list**: This setting controls which set of resource properties are displayed in the classification tab in your resource location. (see resource properties list section below)

To edit group policy settings for manual classification:

1. Open Group Policy Management, select your domain, and then click **Domain Controllers**.
2. Right-click **Default Domain Controllers Policy**, and then click **Edit**.
3. **To enable group policy settings to display Classification tab in File Explorer**:

   In the Group Policy Management Editor window, double-click **Computer Configuration**,

double-click **Policies**, double-click **Administrative Templates**, double-click **System**, and then double-click **File Classification Infrastructure**.

4. Double-click **File Classification Infrastructure: Display Classification tab in File Explorer**. In the File Classification Infrastructure: Display Classification tab in File Explorer dialog box, select **Enabled**
5. **To enable group policy setting to specify classification properties list**:

   Double-click **File Classification Infrastructure: Specify classification properties list**. In the File Classification Infrastructure: Specify classification properties list dialog box, select **Global Properties list** and then select **Enabled**.

   Note
   Specify the resource property list you want displayed in the **Classification Properties list** box. By default, the Global Resource Properties List is used if you do not specify anything in the **Classification Properties List** box.
6. Close Group Policy Management.
7. On the Windows 8 client, open a command prompt and type **gpupdate /force**.

Classify files and folders manually

To manually classify files and folder

1. Navigate to the folder on your file server that contains files that you want to classify.
2. Right-click a file in that folder, and then click Properties.
3. Click the Classification tab, select the resource property you want to tag the folder and click the value, and click OK.

Classification properties lists

To allow you to expose different sets of classification properties to different users, you can create classification properties lists that contain specific resource properties. For example, you might want all the HR employees to set a resource property called “HR file type” and the finance department employees to set a resource property called “Finance file type”

In order to expose HR and Finance with different resource properties, you can create two classification properties lists in the Dynamic Access Control node in Active Directory and populate them with the appropriate resource properties (note that the built-in Global properties list is populated by default)Then in the group policy for the HR department, use the “HR properties list” and for the Finance department, use the “Finance properties list”

Scenario: Implement Retention of Information on File Servers

A retention period is the amount of time that a document should be kept before it is expired. Depending on the organization, the retention period can be different. You can classify files in a folder as having a short, medium, or long-term retention period, and then assign a timeframe for each period. You may want to keep a file indefinitely by putting it on legal hold.

Scenario description

File Classification Infrastructure and File Server Resource Manager uses file management tasks and file classification to apply retention periods for a set of files. You can assign a retention period on a folder and then use a file management task to configure how long an assigned retention period is to last. When the files in the folder are about to expire, the owner of the file receives a notification email. You can also classify a file as being on legal hold so that the file management task will not expire the file.

You can find planning information for configuring retention in Plan for Retention of Information on File Servers.

You can find steps for classifying files for legal hold and configuring a retention period in Deploy Implementing Retention of Information on File Servers (Demonstration Steps).

Note
That scenario only discusses how to manually classify a document for legal hold. However, it is possible in Windows Server 2012 to automatically classify documents for legal hold. One way to do this is to create a Windows PowerShell classifier that compares the file owner to a list of user accounts that are under legal hold. If the file owner is a part of the user account list, the file is classified for legal hold.

In this scenario

This scenario is part of the Dynamic Access Control scenario. For additional information about Dynamic Access Control, see:

- Dynamic Access Control: Scenario Overview

Features included in this scenario

The following table lists the features that are part of this scenario and describes how they support it.

Feature	How it supports this scenario
File Server Resource Manager Overview	File Management Tasks is a feature that is

Feature	How it supports this scenario
	included in File Server Resource Manager.
File and Storage Services Overview	File Server Resource Manager is a feature that is included with the File Services server role.

Plan for Retention of Information on File Servers

A data retention policy is important for any organization.

Use the following table to plan how you retain information in your organization.

Task	Description
1.1. Determine the retention schedule	Determining how long to retain data reduces your storage requirements, reduces liability, and satisfies regulations.
1.2. Identify files to be retained	Before you implement a data retention policy, you must first know the type of data that is stored on each file server in your organization.
1.3 Considerations for multiple computers	Use the Data Classification Toolkit when possible to export the configuration from a baseline computer and import it on the file servers.

1.1. Determine the retention schedule

Determining how long data is stored on file servers in your network and developing a data retention schedule offers the following advantages:

- Limits the amount of data to store which lowers the overall cost of storage in your organization
- Reduces liability
- Satisfies regulations

When you are determining your retention schedule, you should consult an attorney to ensure that the retention schedule meets the regulatory compliance of the industry your organization is in. For example, if your company is a healthcare provider, you should understand the HIPAA regulations.

1.2. Identify files to be retained

Before you can implement your data retention policy, you must first identify the data that is stored on each file server. Once the data has been identified, you should mark the folders with a retention period and retention start date. Also, you should remove the Delete Child permission from any folders that could contain files that are being retained. This will ensure that the files are not accidentally deleted.

Important
Classification properties should not be specified as a date. You should use the retention period to classify the file. If the retention period should change, you can update the retention period interval without having to classify every file again.

1.3 Considerations for multiple computers

There are several things to consider when you have more than one file server in your organization:

- Data retention policies are usually the same across the organization so you can reuse the same set of rules on multiple computers.
- The Data Classification Toolkit uses Windows PowerShell cmdlets to import and export classification rules. You should be this to export the configuration from a baseline computer and import to another computer to ensure that the configuration is the same.
- You should use dynamic name spaces when the source and destination servers use the same drive letters for the storage on the server. When you create a new file share by using Server Manager, you can specify the name space. For more information about dynamic name spaces, see What's New in File Server Resource Manager in Windows Server 2012.

Deploy Implementing Retention of Information on File Servers (Demonstration Steps)

You can set retention periods for folders and put files on legal hold by using File Classification Infrastructure and File Server Resource Manager.

In this document

- **Prerequisites**

- **Step 1: Create resource property definitions**
- Step 2: Configure notifications
- **Step 3: Create a file management task**
- Step 4: Classify a file manually

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

Prerequisites

The steps in this topic assume you have a SMTP server configured for file expiration notifications.

Step 1: Create resource property definitions

In this step, we enable the Retention Period and Discoverability resource properties so that File Classification Infrastructure can use these resource properties to tag the files that are scanned in a network shared folder.

Do this step using Windows PowerShell

To create resource property definitions

1. On the domain controller, sign in to the server as a member of the Domain Admins security group.
2. Open Active Directory Administrative Center. In Server Manager, click **Tools**, and then click **Active Directory Administrative Center**.
3. Expand **Dynamic Access Control**, and then click **Resource Properties**.
4. Right-click **Retention Period**, and then click **Enable**.
5. Right-click **Discoverability**, and then click **Enable**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-ADResourceProperty -Enabled:$true -Identity:"CN=RetentionPeriod_MS,CN=Resource
Properties,CN=Claims Configuration,CN=Services,CN=Configuration,DC=contoso,DC=com"
Set-ADResourceProperty -Enabled:$true -Identity:"CN=Discoverability_MS,CN=Resource
Properties,CN=Claims Configuration,CN=Services,CN=Configuration,DC=contoso,DC=com"
```

Step 2: Configure notifications

In this step, we use the File Server Resource Manager console to configure the SMTP server, the default administrator email address, and the default email address that the reports are sent from.

Do this step using Windows PowerShell

To configure notifications

1. Sign in to the file server as a member of the Administrators security group.
2. From the Windows PowerShell command prompt, type **Update-FsrmClassificationPropertyDefinition**, and then press ENTER. This will synchronize the property definitions that are created on the domain controller to the file server.
3. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
4. Right-click **File Server Resource Manager (local)**, and then click **Configure Options**.
5. On the **Email Notifications** tab, configure the following:
   - In the **SMTP server name or IP address** box, type the name of the SMTP server on your network.
   - In the **Default administrator recipients** box, type the email address of the administrator who should get the notification.
   - In the **Default "From" e-mail address** box, type the email address that should be used to send the notifications.
6. Click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Set-FsrmSetting -SmtpServer IP address of SMTP server -FromEmailAddress
"FromEmailAddress" -AdminEmailAddress "AdministratorEmailAddress"
```

Step 3: Create a file management task

In this step, we use the File Server Resource Manager console to create a file management task that will run on the last day of the month and expire any files with the following criteria:

- The file is not classified as being on legal hold.
- The file is classified as having a long-term retention period.
- The file has not been modified in the last 10 years.

Do this step using Windows PowerShell

To create a file management task

1. Sign in to the file server as a member of the Administrators security group.
2. Open File Server Resource Manager. In Server Manager, click **Tools**, and then click **File Server Resource Manager**.
3. Right-click **File Management Tasks**, and then click **Create File Management Task**.
4. On the **General** tab, in the **Task name** box, type a name for the file management task,

such as Retention Task.

5. On the **Scope** tab, click **Add**, and choose the folders that should be included in this rule, such as D:\Finance Documents.
6. On the **Action** tab, in the **Type** box, click **File expiration**. In the **Expiration directory** box, type a path to a folder on the local file server where the expired files will be moved. This folder should have an access control list that grants only file server administrators access.
7. On the **Notification** tab, click **Add**.
   - Select the **Send e-mail to the following administrators** check box.
   - Select the **Send an email to users with affected files** check box, and then click **OK**.
8. On the **Condition** tab, click **Add**, and add the following properties:
   - In the **Property** list, click **Discoverability**. In the **Operator** list, click **Not equal**. In the **Value** list, click **Hold**.
   - In the **Property** list, click **Retention Period**. In the **Operator** list, click **Equal**. In the **Value** list, click **Long-Term**.
9. On the **Condition** tab, select the **Days since file was last modified** check box, and then set the value to **3650**.
10. On the **Schedule** tab, click the **Monthly** option, and then select the **Last** check box.
11. Click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
$fmjexpiration = New-FSRMFmjAction -Type 'Expiration' -ExpirationFolder folder

$fmjNotificationAction = New-FsrmFmjNotificationAction -Type Email -MailTo
"[FileOwner],[AdminEmail]"

$fmjNotification = New-FsrmFMJNotification -Days 10 -Action @($fmjNotificationAction)

$fmjCondition1 = New-FSRMFmjCondition -Property 'Discoverability_MS' -Condition
'NotEqual' -Value "Hold"

$fmjCondition2 = New-FSRMFmjCondition -Property 'RetentionPeriod_MS' -Condition 'Equal' -
Value "Long-term"

$fmjCondition3 = New-FSRMFmjCondition -Property 'File.DateLastAccessed' -Condition
'Equal' -Value 3650

$date = get-date
$schedule = New-FsrmScheduledTask -Time $date -Monthly @(-1)

$fmj1=New-FSRMFileManagementJob -Name "Retention Task" -Namespace @('D:\Finance
Documents') -Action $fmjexpiration -Schedule $schedule -Notification @($fmjNotification)
-Condition @( $fmjCondition1, $fmjCondition2, $fmjCondition3)
```

Step 4: Classify a file manually

In this step, we manually classify a file to be on legal hold. The parent folder of this file will be classified with a long-term retention period.

To manually classify a file

1. Sign in to the file server as a member of the Administrators security group.
2. Navigate to the folder that was configured in the scope of the file management task created in Step 3.
3. Right-click the folder, and then click **Properties**.
4. On the **Classification** tab, click **Retention Period**, click **Long-Term**, and then click **OK**.
5. Right-click a file within that folder, and then click **Properties**.
6. On the **Classification** tab, click **Discoverability**, click **Hold**, click **Apply**, and then click **OK**.
7. On the file server, run the file management task by using the File Server Resource Manager console. After the file management task completes, check the folder and ensure the file was not moved to the expiration directory.
8. Right-click the same file within that folder, and then click **Properties**.
9. On the **Classification** tab, click **Discoverability**, click **Not Applicable**, click **Apply**, and then click **OK**.
10. On the file server, run the file management task again by using the File Server Resource Manager console. After the file management task completes, check the folder and ensure that file was moved to the expiration directory.

Appendix A: Dynamic Access Control Glossary

Following are the list of terms and definitions that are included in the Dynamic Access Control scenario.

Term	Definition
Automatic classification	Classification that occurs based on classification properties that are determined by

Term	Definition
	classification rules configured by an administrator.
CAPID	Central access policy ID. This ID references a specific central access policy, and it is used to reference the policy from the security descriptor of files and folders.
Central access rule	A rule that includes a condition and an access expression.
Central access policy	Policies that are authored and hosted in Active Directory.
Claims-based access control	A paradigm that utilizes claims to make access control decisions to resources.
Classification	The process of determining the classification properties of resources and assigning these properties to the metadata that is associated with the resources. See also Automatic classification, Inherited classification, and Manual classification.
Device claim	A claim that is associated with the system. With user claims, it is included in the token of a user attempting to access a resource.
Discretionary access control list (DACL)	An access control list that identifies trustees who are allowed or denied access to a securable resource. It can be modified at the discretion of the resource owner.
Resource property	Properties (such as labels) that describe a file and are assigned to files by using automatic classification or manual classification. Examples include: Sensitivity, Project, and Retention period.
File Server Resource Manager	A feature in the Windows Server operating system that offers management of folder quotas, file screening, storage reports, file classification, and file management jobs on a file server.
Folder properties and labels	Properties and labels that describe a folder and are assigned manually by administrators and

Term	Definition
	folder owners. These properties assign default property values to the files within these folders, for example, Secrecy or Department.
Group Policy	A set of rules and policies that controls the working environment of users and computers in an Active Directory environment.
Near real time classification	Automatic classification that is performed shortly after a file is created or modified.
Near real-time file management tasks	File management tasks that are performed shortly after (a file is created or modified. These tasks are triggered by the Near real-time classification.
Organizational Unit (OU)	An Active Directory container that represents hierarchical, logical structures within an organization. It is the smallest scope to which Group Policy settings are applied.
Secure property	A classification property that the authorization runtime can trust to be a valid assertion about the resource at a certain point-in-time. In claims-based access control, a secure property that is assigned to a resource is treated as a resource claim.
Security descriptor	A data structure that contains security information associated with a securable resource, such as access control lists.
Security descriptor definition language	A specification that describes the information in a security descriptor as a text string.
Staging policy	A central access policy that is not yet in effect.
System access control list (SACL)	An access control list that specifies the types of access attempts by particular trustees for which audit records need to be generated.
User claim	Attributes of a user that are provided within the user security token. Examples include: Department, Company, Project, and Security clearance. Information in the user token from systems prior to Windows Server 2012, such as the security groups that the user is part of, can

Term	Definition
	also be considered user claims. Some user claims are provided through Active Directory and others are calculated dynamically, such as whether the user logged in with a smart card.
User token	A data object that identifies a user and the user claims and device claims that are associated with that user. It is used to authorize the user's access to resources.

Dynamic Access Control: Scenario Overview

Appendix B: Setting Up the Test Environment

This topic outlines the steps to build a hands-on lab to test Dynamic Access Control. The instructions are meant to be followed sequentially because there are many components that have dependencies.

Prerequisites

Hardware and software requirements

Requirements for setting up the test lab:

- A host server running Windows Server 2008 R2 with SP1 and Hyper-V
- A copy of the Windows Server 2012 ISO
- A copy of the Windows 8 ISO
- Microsoft Office 2010
- A server running Microsoft Exchange Server 2003 or later

You need to build the following virtual machines to test the Dynamic Access Control scenarios:

- DC1 (domain controller)
- DC2 (domain controller)
- FILE1 (file server and Active Directory Rights Management Services)
- SRV1 (POP3 and SMTP server)
- CLIENT1 (client computer with Microsoft Outlook)

The passwords for the virtual machines should be as follows:

- BUILTIN\Administrator: pass@word1
- Contoso\Administrator: pass@word1

- All other accounts: pass@word1

Build the test lab virtual machines

Install the Hyper-V role

You need to install the Hyper-V role on a computer running Windows Server 2008 R2 with SP1.

To install the Hyper-V Role

1. Click **Start**, and then click Server Manager.
2. In the Roles Summary area of the Server Manager main window, click **Add Roles**.
3. On the **Select Server Roles** page, click **Hyper-V**.
4. On the **Create Virtual Networks** page, click one or more network adapters if you want to make their network connection available to virtual machines.
5. On the **Confirm Installation Selections** page, click **Install**.
6. The computer must be restarted to complete the installation. Click **Close** to finish the wizard, and then click **Yes** to restart the computer.
7. After you restart the computer, sign in with the same account you used to install the role. After the Resume Configuration Wizard completes the installation, click **Close** to finish the wizard.

Create an internal virtual network

Now you will create an internal virtual network called ID_AD_Network.

To create a virtual network

1. Open Hyper-V Manager.
2. From the **Actions** menu, click **Virtual Network Manager**.
3. Under **Create virtual network**, select the **Internal**.
4. Click **Add**. The **New Virtual Network** page appears.
5. Type **ID_AD_Network** as the name for the new network. Review the other properties and modify them if necessary.
6. Click **OK** to create the virtual network and close Virtual Network Manager, or click **Apply** to create the virtual network and continue using Virtual Network Manager.

Build the domain controller

Build a virtual machine to be used as the domain controller (DC1). Install the virtual machine using Windows Server 2012 ISO, and name it DC1.

To install Active Directory Domain Services

1. Connect the virtual machine to the ID_AD_Network. Sign in to the DC1 as Administrator with the password **pass@word1**.
2. In Server Manager, click **Manage**, and then click **Add Roles and Features**.
3. On the **Before you begin** page, click **Next**.
4. On the **Select installation type** page, click **Role-based or Feature-based Install**, and then click **Next**.
5. On the **Select destination server** page, click **Next**.
6. On the **Select server roles** page, click **Active Directory Domain Services**. In the **Add Roles and Features Wizard** dialog box, click **Add Features**, and then click **Next**.
7. On the **Select features** page, click **Next**.
8. On the **Active Directory Domain Services** page, review the information, and then click **Next**.
9. On the **Confirm installation selections** page, click **Install**. The Feature installation progress bar on the Results page indicates that the role is being installed.
10. On the **Results** page, verify that the installation succeeded, and click **Close**. In Server Manager, click the warning icon with an exclamation mark on top right corner of the screen, next to **Manage**. In the Tasks list, click the **Promote this server to a domain controller** link.
11. On the **Deployment Configuration** page, click **Add a new forest**, type the name of the root domain, **contoso.com**, and then click **Next**.
12. On the **Domain Controller Options** page, select the domain and forest functional levels as Windows Server 2012, specify the DSRM password **pass@word1**, and then click **Next**.
13. On the **DNS Options** page, click **Next**.
14. On the **Additional Options** page, click **Next**.
15. On the **Paths** page, type the locations for the Active Directory database, log files, and SYSVOL folder (or accept default locations), and then click **Next**.
16. On the **Review Options** page, confirm your selections, and then click **Next**.
17. On the **Prerequisites Check** page, confirm that the prerequisites validation is completed, and then click **Install**.
18. On the **Results** page, verify that the server was successfully configured as a domain controller, and then click **Close**.
19. Restart the server to complete the AD DS installation. (By default, this happens automatically.)

Create the following users by using Active Directory Administrative Center.

Create users and groups on DC1

1. Sign in to contoso.com as Administrator. Launch Active Directory Administrative Center.
2. Create the following security groups:

Group Name	Email Address
FinanceAdmin	financeadmin@contoso.com
FinanceException	financeexception@contoso.com

3. Create the following organizational unit (OU):

OU Name	Computers
FileServerOU	FILE1

4. Create the following users with the attributes indicated:

User	Username	Email address	Department	Group	Country/Region
Myriam Delesalle	MDelesalle	MDelesalle@contoso.com	Finance		US
Miles Reid	MReid	MReid@contoso.com	Finance	FinanceAdmin	US
Esther Valle	EValle	EValle@contoso.com	Operations	FinanceException	US
Maira Wenzel	MWenzel	MWenzel@contoso.com	HR		US
Jeff Low	JLow	JLow@contoso.com	HR		US
RMS Server	rms	rms@contoso.com			

For more information about creating security groups, see Create a New Group on the Windows Server website.

To create a Group Policy Object

1. Hover the cursor on the upper right corner of screen and click the search icon. In the Search box, type **group policy management**, and click **Group Policy Management**.
2. Expand **Forest: contoso.com**, and then expand **Domains**, navigate to **contoso.com**, expand **(contoso.com)**, and then select **FileServerOU**. Right-click **Create a GPO in this domain and Link it here…**

3. Type a descriptive name for the GPO, such as **FlexibleAccessGPO**, and then click **OK**.

To enable Dynamic Access Control for contoso.com

1. Open the Group Policy Management Console, click **contoso.com**, and then double-click **Domain Controllers**.
2. Right-click **Default Domain Controllers Policy**, and select **Edit**.
3. In the Group Policy Management Editor window, double-click **Computer Configuration**, double-click **Policies**, double-click **Administrative Templates**, double-click **System**, and then double-click **KDC**.
4. Double-click **KDC support for claims, compound authentication, and Kerberos armoring** and select the option next to **Enabled**. You need to enable this setting to use Central Access Policies.
5. Open an elevated command prompt, and run the following command:

```
gpupdate /force
```

Build the file server and AD RMS server (FILE1)

1. Build a virtual machine with the name FILE1 from the Windows Server 2012 ISO.
2. Connect the virtual machine to the ID_AD_Network.
3. Join the virtual machine to the contoso.com domain, and then sign in to FILE1 as contoso\administrator using the password **pass@word1**.

Install File Services Resource Manager

To install the File Services role and the File Server Resource Manager

1. In Server Manager, click **Add Roles and Features**.
2. On the **Before you begin** page, click **Next**.
3. On the **Select installation type** page, click **Next**.
4. On the **Select destination server** page, click **Next**.
5. On the **Select Server Roles** page, expand **File and Storage Services**, select the check-box next to **File and iSCSI Services**, expand, and select **File Server Resource Manager**.

   In the Add Roles and Features Wizard, click **Add Features**, and then click **Next**.
6. On the **Select features** page, click **Next**.
7. On the **Confirm installation selections** page, click **Install**.
8. On the **Installation progress** page, click **Close**.

Install the Microsoft Office Filter Packs on the file server

You should install the Microsoft Office Filter Packs on Windows Server 2012 to enable IFilters for a wider array of Office files than are provided by default. Windows Server 2012 does not have

any IFilters for Microsoft Office Files installed by default, and the file classification infrastructure uses IFilters to perform content analysis.

To download and install the IFilters, see Microsoft Office 2010 Filter Packs.

Configure email notifications on FILE1

When you create quotas and file screens, you have the option of sending email notifications to users when their quota limit is approaching or after they have attempted to save files that have been blocked. If you want to routinely notify certain administrators of quota and file screening events, you can configure one or more default recipients. To send these notifications, you must specify the SMTP server to be used for forwarding the email messages.

To configure email options in File Server Resource Manager

1. Open File Server Resource Manager. To open File Server Resource Manager, click **Start**, type **file server resource manager**, and then click **File Server Resource Manager**.
2. In the File Server Resource Manager interface, right-click **File Server Resource Manager**, and then click **Configure options**. The **File Server Resource Manager Options** dialog box opens.
3. On the **E-mail Notifications** tab, under SMTP server name or IP address, type the host name or the IP address of the SMTP server that will forward email notifications.
4. If you want to routinely notify certain administrators of quota or file screening events, under **Default administrator recipients**, type each email address such as fileadmin@contoso.com. Use the format account@domain, and use semicolons to separate multiple accounts.

Create groups on FILE1

To create security groups on FILE1

1. Sign in to FILE1 as contoso\administrator, with the password: **pass@word1**.
2. Add NT AUTHORITY\Authenticated Users to the **WinRMRemoteWMIUsers__** group.

Create files and folders on FILE1

1. Create a new NTFS volume on FILE1 and then create the following folder: D:\Finance Documents.
2. Create the following files with the details specified:
   - **Finance Memo.docx**: Add some finance related text in the document. For example, “The business rules about who can access finance documents have changed. Finance documents are now only accessed by members of the FinanceExpert group. No other departments or groups have access.” You need to evaluate the impact of this change before implementing it in the environment. Ensure that this document has CONTOSO CONFIDENTIAL as the footer on every page.

- **Request for Approval to Hire.docx**: Create a form in this document that collects applicant information. You must have the following fields in the document: **Applicant Name, Social Security number, Job Title, Proposed Salary, Starting Date, Supervisor name, Department**. Add an additional section in the document that has a form for **Supervisor Signature, Approved Salary, Conformation of Offer**, and **Status of Offer**.
  Make the document rights-management enabled.
- **Word Document1.docx**: Add some test content to this document.
- **Word Document2.docx**: Add test content to this document.
- **Workbook1.xlsx**
- **Workbook2.xlsx**
- Create a folder on the desktop called Regular Expressions. Create a text document under the folder called **RegEx-SSN**. Type the following content in the file, and then save and close the file:
  ^(?!000)([0-7]\d{2}|7([0-7]\d|7[012]))([-]?)(?!00)\d\d\3(?!0000)\d{4}$

3. Share the folder D:\Finance Documents as Finance Documents and allow everyone to have Read and Write access to the share.

Note
Central access policies are not enabled by default on the system or boot volume C:.

Install Active Directory Rights Management Services

Add the Active Directory Rights Management Services (AD RMS) and all required features through Server Manager. Choose all the defaults.

To install Active Directory Rights Management Services

1. Sign in to the FILE1 as CONTOSO\Administrator or as a member of the Domain Admins group.

   Important
   In order to install the AD RMS server role the installer account (in this case, CONTOSO\Administrator) will have to be given membership in both the local Administrators group on the server computer where AD RMS is to be installed as well as membership in the Enterprise Admins group in Active Directory.
2. In Server Manager, click **Add Roles and Features**. The Add Roles and Features Wizard appears.
3. On the **Before you Begin** screen, click **Next**.
4. On the **Select Installation Type** screen, click **Role/Feature Based Install**, and then click **Next**.
5. On the **Select Server Targets** screen, click **Next**.
6. On the **Select Server Roles** screen, select the box next to **Active Directory Rights Management Services**, and then click **Next**.

7. In the **Add features that are required for Active Directory Rights Management Services?** dialog box, click **Add Features**.
8. On the **Select Server Roles** screen, click **Next**.
9. On the **Select Features to Install** screen, click **Next**.
10. On the **Active Directory Rights Management Services** screen, click Next.
11. On the **Select Role Services** screen, click **Next**.
12. On the **Web Server Role (IIS)** screen, click **Next**.
13. On the **Select Role Services** screen, click **Next**.
14. On the **Confirm Installation Selections** screen, click **Install**.
15. After the installation has completed, on the **Installation Progress** screen, click **Perform additional configuration**. The AD RMS Configuration Wizard appears.
16. On the **AD RMS** screen, click **Next**.
17. On the **AD RMS Cluster** screen, select **Create a new AD RMS root cluster** and then click **Next**.
18. On the **Configuration Database** screen, click **Use Windows Internal Database on this server**, and then click **Next**.

    Note

    Using the Windows Internal Database is recommended for test environments only because it does not support more than one server in the AD RMS cluster. Production deployments should use a separate database server.
19. On the **Service Account** screen, in **Domain User Account**, click **Specify** and then specify the user name (**contoso\rms**), and Password (**pass@word1**) and click **OK**, and then click **Next**.
20. On the **Cryptographic Mode** screen, click **Cryptographic Mode 2**.
21. On the **Cluster Key Storage** screen, click **Next**.
22. On the **Cluster Key Password** screen, in the **Password** and **Confirm password** boxes, type **pass@word1**, and then click **Next**.
23. On the **Cluster Web Site** screen, make sure that **Default Web Site** is selected, and then click **Next**.
24. On the **Cluster Address** screen, select the **Use an unencrypted connection** option, in the **Fully Qualified Domain Name** box, type **FILE1.contoso.com**, and then click **Next**.
25. On the **Licensor Certificate Name** screen, accept the default name (**FILE1**) in the text box and click **Next**.
26. On the **SCP Registration** screen, select **Register SCP now**, and then click **Next**.
27. On the **Confirmation** screen, click **Install**.
28. On the **Results** screen, click **Close**, and then click **Close** on **Installation Progress** screen. When complete, log off and log on as contoso\rms using the password provided (**pass@word1**).
29. Launch the AD RMS console and navigate to **Rights Policy Templates**.

    To open the AD RMS console, in Server Manager, click **Local Server** in the console tree,

then click **Tools**, and then click **Active Directory Rights Management Services**.

30. Click the **Create Distributed Rights Policy** template located on the right panel, click **Add**, and select the following information:
    - Language: US English
    - Name: Contoso Finance Admin Only
    - Description: Contoso Finance Admin Only

    Click **Add**, and then click **Next**.
31. Under the Users and Rights section, click **Users and rights**, click **Add**, type **financeadmin@contoso.com**, and click **OK**.
32. Select **Full Control**, and leave **Grant owner (author) full control right with no expiration** selected.
33. Click though the remaining tabs with no changes, and then click **Finish**. Sign in as CONTOSO\Administrator.
34. Browse to the folder, C:\inetpub\wwwroot_wmcs\certification, select the ServerCertification.asmx file, and add Authenticated Users to have Read and Write permissions to the file.
35. Open Windows PowerShell and run `Get-FsrmRmsTemplate`. Verify that you are able to see the RMS template you created in the previous steps in this procedure with this command.

Important

If you want your file servers to immediately change so you can test them, you need to do the following:

1. On the file server, FILE1, open an elevated command prompt, and run the following commands:
   - gpupdate /force.
   - NLTEST /SC_RESET:contoso.com
2. On the domain controller (DC1), replicate Active Directory.

   For more information about steps to force the replication of Active Directory, see Active Directory Replication

Optionally, instead of using the Add Roles and Features Wizard in Server Manager, you can use Windows PowerShell to install and configure the AD RMS server role as show in the following procedure.

To install and configure an AD RMS cluster in Windows Server 2012 using Windows PowerShell

1. Logon on as CONTOSO\Administrator with the password: **pass@word1**.

   Important

   In order to install the AD RMS server role the installer account (in this case, CONTOSO\Administrator) will have to be given membership in both the local Administrators group on the server computer where AD RMS is to be installed as

well as membership in the Enterprise Admins group in Active Directory.

2. On the Server desktop, right-click the Windows PowerShell icon on the taskbar and select **Run as Administrator** to open a Windows PowerShell prompt with administrative privileges.
3. To use Server Manager cmdlets to install the AD RMS server role, type:

```
Add-WindowsFeature ADRMS –IncludeAllSubFeature –
IncludeManagementTools
```

4. Create the Windows PowerShell drive to represent the AD RMS server you are installing.

   For example, to create a Windows PowerShell drive named RC to install and configure the first server in an AD RMS root cluster, type:

```
Import-Module ADRMS
New-PSDrive -PSProvider ADRMSInstall -Name RC -Root
RootCluster
```

5. Set properties on objects in the drive namespace that represent required configuration settings.

   For example, to set the AD RMS service account, at the Windows PowerShell command prompt, type:

```
$svcacct = Get-Credential
```

   When the Windows security dialog box appears, type the AD RMS service account domain user name CONTOSO\RMS and the assigned password.

   Next, to assign the AD RMS service account to the AD RMS cluster settings, type the following:

```
Set-ItemProperty –Path RC:\ –Name ServiceAccount –Value
$svcacct
```

   Next, to set the AD RMS server to use the Windows Internal Database, at the Windows PowerShell command prompt, type:

```
Set-ItemProperty –Path RC:\ClusterDatabase –Name
UseWindowsInternalDatabase –Value $true
```

   Next, to securely store the cluster key password in a variable, at the Windows PowerShell command prompt, type:

```
$password = Read-Host –AsSecureString –Prompt "Password:"
```

   Type the cluster key password, and then press the ENTER key.

   Next, to assign the password to your AD RMS installation, at the Windows PowerShell command prompt, type:

```
Set-ItemProperty –Path RC:\ClusterKey –Name
CentrallyManagedPassword –Value $password
```

   Next, to set the AD RMS cluster address, at the Windows PowerShell command prompt, type:

```
Set-ItemProperty -Path RC:\ -Name ClusterURL -Value
"http://file1.contoso.com:80"
```

Next, to assign the SLC name for your AD RMS installation, at the Windows PowerShell command prompt, type:

```
Set-ItemProperty -Path RC:\ -Name SLCName -Value "FILE1"
```

Next, to set the service connection point (SCP) for the AD RMS cluster, at the Windows PowerShell command prompt, type:

```
Set-ItemProperty -Path RC:\ -Name RegisterSCP -Value $true
```

6. Run the **Install-ADRMS** cmdlet. In addition to installing the AD RMS server role and configuring the server, this cmdlet also installs other features required by AD RMS if necessary.

   For example, to change to the Windows PowerShell drive named RC and install and configure AD RMS, type:

   ```
   Set-Location RC:\
   Install-ADRMS –Path.
   ```

   Type "Y" when the cmdlet prompts you to confirm you want to start the installation.

7. Log out as CONTOSO\Administrator and log on as CONTOSO\RMS using the provided password ("pass@word1").

   Important
   In order to manage the AD RMS server the account you are logged on to and using to manage the server (in this case, CONTOSO\RMS) will have to be given membership in both the local Administrators group on the AD RMS server computer as well as membership in the Enterprise Admins group in Active Directory.

8. On the Server desktop, right-click the Windows PowerShell icon on the taskbar and select **Run as Administrator** to open a Windows PowerShell prompt with administrative privileges.
9. Create the Windows PowerShell drive to represent the AD RMS server you are configuring.

   For example, to create a Windows PowerShell drive named RC to configure the AD RMS root cluster, type:

   ```
   Import-Module ADRMSAdmin `
   New-PSDrive -PSProvider ADRMSAdmin -Name RC -Root
   http://localhost -Force -Scope Global
   ```

10. To create new rights template for the Contoso finance administrator and assign it user rights with full control in your AD RMS installation, at the Windows PowerShell command prompt, type:

    ```
    New-Item -Path RC:\RightsPolicyTemplate –LocaleName en-us -
    DisplayName "Contoso Finance Admin Only" -Description
    ```

```
"Contoso Finance Admin Only" -UserGroup
financeadmin@contoso.com  -Right ('FullControl')
```

11. To verify that you can see the new rights template for the Contoso finance administrator, at the Windows PowerShell command prompt:

    ```
    Get-FsrmRmsTemplate
    ```

    Review the output of this cmdlet to confirm the RMS template you created in the previous step is present.

Build the mail server (SRV1)

SRV1 is the SMTP/POP3 mail server. You need to set it up so that you can send email notifications as part of the Access-Denied assistance scenario.

Configure Microsoft Exchange Server on this computer. For more information, see How to Install Exchange Server.

Build the client virtual machine (CLIENT1)

To build the client virtual machine

1. Connect the CLIENT1 to the ID_AD_Network.
2. Install Microsoft Office 2010.
3. Sign in as Contoso\Administrator, and use the following information to configure Microsoft Outlook.
   - Your name: File Administrator
   - Email address: fileadmin@contoso.com
   - Account type: POP3
   - Incoming mail server: Static IP address of SRV1
   - Outgoing mail server: Static IP address of SRV1
   - User name: fileadmin@contoso.com
   - Remember password: Select
4. Create a shortcut to Outlook on the contoso\administrator desktop.
5. Open Outlook and address all the “first time launched” messages.
6. Delete any test messages that were generated.
7. Create a new short cut on desktop for all users on the client virtual machine that points to \\FILE1\Finance Documents.
8. Reboot as needed.

Enable Access-Denied assistance on the client virtual machine

1. Open Registry Editor, and navigate to

HKEY_LOCAL_MACHINE\SOFTWARE\Policies\Microsoft\Windows\Explorer.

- Set **EnableShellExecuteFileStreamCheck** to **1**.
- Value: DWORD

Lab setup for deploying claims across forests scenario

Build a virtual machine for DC2

- Build a virtual machine from the Windows Server 2012 ISO.

- Create the virtual machine name as DC2.
- Connect the virtual machine to the ID_AD_Network.

Important

Joining virtual machines to a domain and deploying claim types across forests require that the virtual machines be able to resolve the FQDNs of the relevant domains. You may have to manually configure the DNS settings on the virtual machines to accomplish this. For more information, see Configuring a virtual network.

All the virtual machine images (servers and clients) must be reconfigured to use a static IP version 4 (IPv4) address and Domain Name System (DNS) client settings. For more information, see Configure a DNS Client for Static IP Address.

Set up a new forest called adatum.com

To install Active Directory Domain Services

1. Connect the virtual machine to the ID_AD_Network. Sign in to the DC2 as Administrator with the password **Pass@word1**.
2. In Server Manager, click **Manage**, and then click **Add Roles and Features**.
3. On the **Before you begin** page, click **Next**.
4. On the **Select Installation Type** page, click **Role-based or Feature-based Install**, and then click **Next**.
5. On the **Select destination server** page, click **Select a server from the server pool**, click the names of the server where you want to install Active Directory Domain Services (AD DS), and then click **Next**.
6. On the **Select Server Roles** page, click **Active Directory Domain Services**. In the **Add Roles and Features Wizard** dialog box, click **Add Features**, and then click **Next**.
7. On the **Select Features** page, click **Next**.
8. On the **AD DS** page, review the information, and then click **Next**.
9. On the **Confirmation** page, click **Install**. The Feature installation progress bar on the

Results page indicates that the role is being installed.

10. On the **Results** page, verify that the installation succeeded, and then click the warning icon with an exclamation mark on top right corner of the screen, next to **Manage**. In the Tasks list, click the **Promote this server to a domain controller** link.

    Important
    If you close the installation wizard at this point rather than click **Promote this server to a domain controller**, you can continue the AD DS installation by clicking **Tasks** in Server Manager.

11. On the **Deployment Configuration** page, click **Add a new forest**, type the name of the root domain, **adatum.com**, and then click **Next**.
12. On the **Domain Controller Options** page, select the domain and forest functional levels as Windows Server 2012, specify the DSRM password **pass@word1**, and then click **Next**.
13. On the **DNS Options** page, click **Next**.
14. On the **Additional Options** page, click **Next**.
15. On the **Paths** page, type the locations for the Active Directory database, log files, and SYSVOL folder (or accept default locations), and then click **Next**.
16. On the **Review Options** page, confirm your selections, and then click **Next**.
17. On the **Prerequisites Check** page, confirm that the prerequisites validation is completed, and then click **Install**.
18. On the **Results** page, verify that the server was successfully configured as a domain controller, and then click **Close**.
19. Restart the server to complete the AD DS installation. (By default, this happens automatically.)

Important

To ensure that the network is configured properly, after you have set up both the forests, you must do the following:

- Sign in to adatum.com as adatum\administrator. Open a Command Prompt window, type **nslookup contoso.com**, and then press ENTER.
- Sign in to contoso.com as contoso\administrator. Open a Command Prompt window, type **nslookup adatum.com**, and then press ENTER.

  If these commands execute without errors, the forests can communicate with each other. For more information on nslookup errors, see the troubleshooting section in the topic Using NSlookup.exe

Set contoso.com as a trusting forest to adatum.com

In this step, you create a trust relationship between the Adatum Corporation site and the Contoso, Ltd. site.

To set Contoso as a trusting forest to Adatum

1. Sign in to DC2 as administrator. On the **Start** screen, type domain.msc.
2. In the console tree, right-click adatum.com, and then click Properties.
3. On the **Trusts** tab, click **New Trust**, and then click **Next**.
4. On the **Trust Name** page, type **contoso.com**, in the Domain Name System (DNS) name field, and then click **Next**.
5. On the **Trust Type** page, click **Forest Trust**, and then click **Next**.
6. On the **Direction of Trust** page, click **Two-way**.
7. On the **Sides of Trust** page, click **Both this domain and the specified domain**, and then click **Next**.
8. Continue to follow the instructions in the wizard.

Create additional users in the Adatum forest

Create the user Jeff Low with the password **pass@word1**, and assign the company attribute with the value **Adatum**.

To create a user with the Company attribute

1. Open an elevated command prompt in Windows PowerShell, and paste the following code:

```
New-ADUser `
-SamAccountName jlow `
-Name "Jeff Low" `
-UserPrincipalName jlow@adatum.com `
-AccountPassword (ConvertTo-SecureString `
-AsPlainText "pass@word1" -Force) `
-Enabled $true `
-PasswordNeverExpires $true `
-Path 'CN=Users,DC=adatum,DC=com' `
-Company Adatum`
```

Create the Company claim type on adataum.com

To create a claim type by using Windows PowerShell

1. Sign in to adatum.com as an administrator.
2. Open an elevated command prompt in Windows PowerShell, and type the following code:

```
New-ADClaimType `
-AppliesToClasses:@('user') `
-Description:"Company" `
-DisplayName:"Company" `
-ID:"ad://ext/Company:ContosoAdatum" `
-IsSingleValued:$true `
-Server:"adatum.com" `
-SourceAttribute:Company `
-SuggestedValues:@((New-Object
Microsoft.ActiveDirectory.Management.ADSuggestedValueEntry("C
ontoso", "Contoso", "")), (New-Object
Microsoft.ActiveDirectory.Management.ADSuggestedValueEntry("A
datum", "Adatum", ""))) `
```

Enable the Company resource property on contoso.com

To enable the Company resource property on contoso.com

1. Sign in to contoso.com as an administrator.
2. In Server Manager, click **Tools**, and then click **Active Directory Administrative Center**.
3. In the left pane of Active Directory Administrative Center, click **Tree View**. In the left pane, click **Dynamic Access Control**, and then double-click **Resource Properties**.
4. Select **Company** from the **Resource Properties** list, right-click and select **Properties**. In the **Suggested Values** section, click **Add** to add the suggested values: Contoso and Adatum, and then click **OK** twice.
5. Select **Company** from the **Resource Properties** list, right-click and select **Enable**.

Enable Dynamic Access Control on adatum.com

To enable Dynamic Access Control for adatum.com

1. Sign in to adatum.com as an administrator.
2. Open the Group Policy Management Console, click **adatum.com**, and then double-click **Domain Controllers**.
3. Right-click **Default Domain Controllers Policy**, and select **Edit**.
4. In the Group Policy Management Editor window, double-click **Computer Configuration**, double-click **Policies**, double-click **Administrative Templates**, double-click **System**, and then double-click **KDC**.

5. Double-click **KDC support for claims, compound authentication, and Kerberos armoring** and select the option next to **Enabled**. You need to enable this setting to use Central Access Policies.
6. Open an elevated command prompt, and run the following command:

```
gpupdate /force
```

Create the Company claim type on contoso.com

To create a claim type by using Windows PowerShell

1. Sign in to contoso.com as an administrator.
2. Open an elevated command prompt in Windows PowerShell, then type the following code:

```
New-ADClaimType -SourceTransformPolicy `
-DisplayName "Company" `
-ID "ad://ext/Company:ContosoAdatum" `
-IsSingleValued $true `
-ValueType "string" `
```

Create the central access rule

To create a central access rule

1. In the left pane of Active Directory Administrative Center, click **Tree View**. In the left pane, click **Dynamic Access Control**, and then click **Central Access Rules**.
2. Right-click **Central Access Rules**, click **New**, and then **Central Access Rule**.
3. In the **Name** field, type **AdatumEmployeeAccessRule**.
4. In the **Permissions** section, select the **Use following permissions as current permissions** option, click **Edit**, and then click **Add**. Click the **Select a principal** link, type **Authenticated Users**, and then click **OK**.
5. In the **Permission Entry for Permissions** dialog box, click **Add a condition**, and enter the following conditions: [**User**] [**Company**] [**Equals**] [**Value**] [**Adatum**]. Permissions should be **Modify, Read and Execute, Read, Write**.
6. Click **OK**.
7. Click **OK** three times to finish and return to Active Directory Administrative Center.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear

word-wrapped across several lines here because of formatting constraints.

```
New-ADCentralAccessRule `
-
CurrentAcl:"O:SYG:SYD:AR(A;;FA;;;OW)(A;;FA;;;BA)(A;;FA;;;SY)(
XA;;0x1301bf;;;AU;(@USER.ad://ext/Company:ContosoAdatum ==
`"Adatum`"))" `
-Name:"AdatumEmployeeAccessRule" `
-ProposedAcl:$null `
-ProtectedFromAccidentalDeletion:$true `
-Server:"contoso.com" `
```

Create the central access policy

To create a central access policy

1. Sign in to contoso.com as an administrator.
2. Open an elevated command prompt in Windows PowerShell, and then paste the following code:

```
New-ADCentralAccessPolicy "Adatum Only Access Policy"
Add-ADCentralAccessPolicyMember "Adatum Only Access Policy" `
-Member "AdatumEmployeeAccessRule" `
```

Publish the new policy through Group Policy

To apply the central access policy across file servers through Group Policy

1. On the **Start** screen, type **Administrative Tools**, and in the **Search** bar, click **Settings**. In the **Settings** results, click **Administrative Tools**. Open the Group Policy Management Console from the **Administrative Tools** folder.

   Tip
   If the **Show Administrative tools** setting is disabled, the Administrative Tools folder and its contents will not appear in the **Settings** results.
2. Right-click the contoso.com domain, click **Create a GPO in this domain and Link it here…**
3. Type a descriptive name for the GPO, such as **AdatumAccessGPO**, and then click **OK**.

To apply the central access policy to the file server through Group Policy

1. On the **Start** screen, type **Group Policy Management**, in the **Search** box. Open **Group Policy Management** from the Administrative Tools folder.

Tip

If the **Show Administrative tools** setting is disabled, the Administrative Tools folder and its contents will not appear in the Settings results.

2. Navigate to and select Contoso as follows: Group Policy Management\Forest: contoso.com\Domains\contoso.com.
3. Right-click the **AdatumAccessGPO** policy, and select **Edit**.
4. In Group Policy Management Editor, click **Computer Configuration**, expand **Policies**, expand **Windows Settings**, and then click **Security Settings**.
5. Expand **File System**, right-click **Central Access Policy**, and then click **Manage Central access policies**.
6. In the **Central Access Policies Configuration** dialog box, click **Add**, select **Adatum Only Access Policy**, and then click **OK**.
7. Close the Group Policy Management Editor. You have now added the central access policy to Group Policy.

Create the Earnings folder on the file server

Create a new NTFS volume on FILE1, and create the following folder: D:\Earnings.

Note

Central access policies are not enabled by default on the system or boot volume C:.

Set classification and apply the central access policy on the Earnings folder

To assign the central access policy on the file server

1. In Hyper-V Manager, connect to server FILE1. Sign in to the server by using Contoso\Administrator, with the password **pass@word1**.
2. Open an elevated command prompt and type: **gpupdate /force**. This will ensure that your Group Policy changes will take effect on your server.
3. You also need to refresh the Global Resource Properties from Active Directory. Open Windows PowerShell, type `Update-FSRMClassificationpropertyDefinition`, and then press ENTER. Close Windows PowerShell.
4. Open Windows Explorer, and navigate to D:\EARNINGS. Right-click the **Earnings** folder, and click **Properties**.
5. Click the **Classification** tab. Select **Company**, and then select **Adatum** in the **Value** field.
6. Click **Change**, select **Adatum Only Access Policy** from the drop-down menu, and then click **Apply**.
7. Click the **Security** tab, click **Advanced**, and then click the **Central Policy** tab. You

should see the **AdatumEmployeeAccessRule** listed. You can expand the item to view all of the permissions that you set when you created the rule in Active Directory.

8. Click **OK** to return to Windows Explorer.

Hosting-Friendly Web Server Platform (IIS): Scenario Overview

This document contains an overview for the hosting-friendly web server, IIS 8, by presenting a collection of scenarios for configuring IIS 8 to support various types of web applications.

Did you mean…

- Building Your Cloud Infrastructure: Scenario Overview
- Web Server (IIS) Overview

Scenario Description

The IIS 8 web server provides a secure, easy-to-manage, modular and extensible platform for reliably hosting websites, services, and applications. The web server scenarios provide end-to-end instructions on how to plan, install, and configure IIS to host various types of services and applications.

Each scenario is self-contained. You can read them in any order and concentrate on those scenarios that most closely meet your needs.

Web Server Scenarios

Scenario	Description
Build a Static Website on IIS	Shows how to install IIS with the minimum module configuration to server static websites. Describes how to add a website, configure anonymous authentication, set up a default document, set up static content compression, use IIS logging, and filter requests.
Build a Classic ASP Website on IIS	Shows how to install IIS with the modules required to server classic ASP websites. Explains how to add a websites and edit ASP application settings.
Build an ASP.NET Website on IIS	Guides you through planning, installing, and configuring an ASP.NET website on IIS.

Scenario	Description
	Describes what IIS modules to install. Shows how to configure ASP.NET settings, such as session state, pages and controls, application settings, .NET compilation and globalization settings. Explains how to configure data source settings. And shows how to improve security with application isolation, .NET trust levels, .NET authentication, machine key settings, and SSL communication.
Build a PHP Website on IIS	Guides you through planning, installing, and configuring a PHP website on IIS. Describes what IIS modules to install. Describes how to configure essential PHP settings. Explains how to configure WinCache and other PHP extensions. Describes how to improve security of a PHP application on IIS.
Build an FTP Site on IIS	Shows how to install FTP on an existing IIS web server. Describes how to add an FTP site, configure FTP site defaults, fire wall support, user isolation, and directory browsing options. Shows how to configure logon attempt restrictions, request filtering, FTP logging, and FTP messages.
Build a Web Farm with IIS Servers	Guides you through planning, installing, and configuring a simple server farm with IIS servers. Helps you plan and configure the farm infrastructure. Shows how set up load balancing by using Application Request Routing (ARR). Describes how to set up shared content and shared configuration. Shows how to set up a central certificate store for SSL certificates. Explains how to set up FTP and Web Deploy on the server farm.

Practical Applications

Whether you are an IT professional, a web developer, or you want to set up your own web server, this scenario can help you install IIS and configure it to serve your web application.

Build a Static Website on IIS

This document guides you through the process of installing an IIS web server and configuring it to serve static content. Static content is a web page (HTML) that is delivered to the user exactly as stored. By contrast, dynamic content is generated by a web application, such as an ASP.NET, classic ASP, or PHP application. Static content displays the same information for all users; dynamic content can display user-specific information, such as the user name.

A static-content web server is the most basic configuration of IIS for supporting HTML websites. You can use a static-content web server to host internal or external (public) websites. When you install IIS 8, the default installation provides all the IIS modules required to support a static-content web server. The default installation includes the ability to serve static HTML files, documents, and images. IIS 8 supports default documents, directory browsing, logging, and anonymous authentication for the static content server.

In this document

- Prerequisites
- Step 1: Install the IIS Web Server
- Step 2: Add a Website

- Step 3: Configure Anonymous Authentication
- Step 4: Configure the Default Documents
- Step 5: Configure Static Content Compression
- Next Steps

Prerequisites

To get the most from this tutorial, you must have access to a computer that is running one of the following operating systems:

- Windows Server® 2012
- Windows® 8

Step 1: Install the IIS Web Server

You can use the Web Platform Installer (Web PI) to install IIS and applications that run on IIS. The Web PI installs the latest versions of web platform offerings, including updates. To learn more about the Web PI, see Learn more and install the Web PI. If you use the Web PI to install IIS, you can skip to step 2.

You can also perform this procedure by using the Windows user interface (UI) or from a command line.

To install IIS on Windows Server 2012 by using the UI

1. On the **Start** page, click the **Server Manager** tile, and then click **OK**.
2. In **Server Manager**, select **Dashboard**, and click **Add roles and features**.
3. In the **Add Roles and Features Wizard**, on the **Before You Begin** page, click **Next**.
4. On the **Select Installation Type** page, select **Role-based or Feature-based Installation** and click **Next**
5. On the **Select Destination Server** page, select **Select a server from the server pool**, select the name of your computer, and click **Next**.
6. On the **Select Server Roles** page, select **Web Server (IIS)**, and then click **Next**.
7. On the **Select Features** page, notice the preselected features, and then click **Next**.
8. On the **Web Server Role (IIS)** page, click **Next**.
9. On the **Select Role Services** page, note the preselected role services, and then click **Next**.

   Note
   Install the IIS 8 default role services for a static-content web server.
10. On the **Confirm Installation Selections** page, confirm your selections, and then click **Install**.
11. On the **Installation Progress** page, confirm that your installation of the Web Server (IIS) role and required role services completed successfully, and then click **Close**.

12. To verify that IIS installed successfully, enter the following into a web browser:

    http://localhost

    You see the default IIS Welcome page.

To install IIS on Windows 8 by using the UI

1. On the **Start** page, type **Control Panel**, and then click the **Control Panel** icon in the search results.
2. In **Control Panel**, click **Programs**, and then click **Turn Windows features on or off**.
3. In the **Windows Features** dialog box, click **Internet Information Services**, and then click **OK**.

   This action installs the IIS 8 default features. Install only the default features for a static-content web server.
4. To verify that IIS installed successfully, enter the following into a web browser:

   http://localhost

   You see the default IIS Welcome page.

To Install IIS by using the command line

- Enter the following command at an elevated command prompt or into a script:

```
Start /w pkgmgr /iu:IIS-WebServerRole;IIS-WebServer;IIS-CommonHttpFeatures;IIS-StaticContent;IIS-DefaultDocument;IIS-DirectoryBrowsing;IIS-HttpErrors;IIS-HealthAndDiagnostics;IIS-HttpLogging;IIS-LoggingLibraries;IIS-RequestMonitor;IIS-Security;IIS-RequestFiltering;IIS-HttpCompressionStatic;IIS-WebServerManagementTools;IIS-ManagementConsole;WAS-WindowsActivationService;WAS-ProcessModel;WAS-NetFxEnvironment;WAS-ConfigurationAPI
```

Step 2: Add a Website

This step tells you how to add a website to IIS by using the IIS Manager UI, or by running Appcmd.exe commands in a command-line window.

To add a website by using the UI

1. Open IIS Manager.
   - For Windows Server 2012, on the **Start** page click the **Server Manager** tile, and then click **OK**. In the **Server Manager**, click the **Tools** menu, and then click **Internet Information Services (IIS) Manager**.
   - For Windows 8, on the **Start** page type **Control Panel**, and then click the **Control Panel** icon in the search results. On the **Control Panel** screen, click **System and Security**, click **Administrative Tools**, and then **click Internet Information Services (IIS) Manager**.
2. In the **Connections** pane, right-click the **Sites** node in the tree, and then click **Add**

Website.

3. In the **Add Website** dialog box, enter a friendly name for your website in the **Site name** box.
4. If you want to select a different application pool than the one listed in the **Application Pool** box, click **Select**. In the **Select Application Pool** dialog box, select an application pool from the **Application Pool** list and then click **OK**.
5. In the **Physical path** box, enter the physical path of the website's folder, or click the browse button (**...**) to navigate the file system to find the folder.
6. If the physical path that you entered in the previous step is to a remote share, click **Connect as** to specify credentials that have permission to access the path. If you do not use specific credentials, select the **Application user (pass-through authentication)** option in the **Connect As** dialog box.
7. Select the protocol for the website from the **Type** list.
8. . If you must specify a static IP address for the website (by default, this is set to **All Unassigned**), enter the IP address in the **IP address** box.
9. Enter a port number in the **Port** text box.
10. Optionally, enter a host header name for the website in the **Host Header** box.
11. If you do not have to make any changes to the site, and you want the website to be immediately available, select the **Start Web site immediately** check box.
12. Click **OK**.

To add a website by using the command line

- Use the following syntax at an elevated command prompt or in a script:

  Note
  For this syntax to work, you either must be in the following directory, or have the directory in your path: `%windir%\system32\inetsrv`

  `appcmd add site /name:string /id:`*`uint`* `/physicalPath:`*`string`* `/bindings:`*`string`*

  The variable `name` is the name, and the variable `id` is a positive integer that you want to assign to the site. The variables `name` and `id` are the only variables that are required to add a site by using appcmd. However, if you add a site without specifying the values for the `bindings` and `physicalPath` attributes, the site will not be able to start.

  The variable `physicalPath` is the absolute path of the site content in the file system.

  The variable `bindings` contains information that is used to access the site. It must be in the form *protocol/IP_Address:port:hostheader*. For example, for a website, the binding `http/*:85:` configures the site to listen for HTTP requests on port 85 for all IP addresses and domain names (also known as host headers or host names). On the other hand, a binding of `http/*:85:`**marketing.contoso.com** configures a website to listen for HTTP requests on port 85 for all IP addresses and for the domain name **marketing.contoso.com**.

  To add a website named **contoso** with an ID of 2 that has content in **c:\contoso**, and

that listens for HTTP requests on port 85 for all IP addresses and a domain name of **marketing.contoso.com**, enter the following at the command prompt:

```
appcmd add site /name:contoso /id:2 /physicalPath:c:\contoso
/bindings:http/*:85:marketing.contoso.com
```

Step 3: Configure Anonymous Authentication

Anonymous authentication gives users access to the public areas of your website without prompting them for a user name or password. You can configure anonymous authentication by using the default anonymous user account (IUSR), or you can set up a local user account for anonymous users.

To configure anonymous authentication by using the UI

1. In **Features View** of IIS Manager, double-click **Authentication**.
2. On the **Authentication** page, select **Anonymous Authentication**.
3. In the **Actions** pane, click **Edit** to set the security principal (user credentials) under which anonymous users will connect to the site.
4. In the **Edit Anonymous Authentication Credentials** dialog box, select one of the following options:
   - If you want to configure a specific user account that IIS uses to access your site or application, select **Specific user**. Then click **Set** to open the **Set Credentials** dialog box, and enter a user name and password for the identity. Then click **OK**.
   - If you want IIS processes to run by using the account that is currently specified on the property page for the application pool, select **Application pool identity**. By default, this identity is the IUSR account.

     Important
     If you use the IUSR account, you grant anonymous users all the internal network access associated with that account.
5. Click **OK** to close the **Edit Anonymous Authentication Credentials** dialog box.

To configure anonymous authentication by using the command line

- Use the following syntax to change the default account for anonymous access:

  `appcmd set config /section:anonymousAuthentication /userName:`*`string`* `/password:`*`string`*

  The variable `username` is the account that IIS uses for anonymous authentication, and the variable `password` is the password, which is encrypted in the configuration file by default. For example, to use an account named **Moe** and a password of **pssword1** for anonymous access, enter the following at the command prompt:

  ```
  appcmd set config /section:anonymousAuthentication /userName:Moe
  /password:pssword1
  ```

Step 4: Configure the Default Documents

When a client request to your website doesn't include a document name, IIS looks for a file whose name is defined as a default document. Typically, the default document name is Default.htm. You can define a list of default document names in order of precedence.

To configure the default document by using the UI

1. In **Features View** of IIS Manager, double-click **Default Document**.
2. In the **Actions** pane, click **Add**.
3. In the **Name** box, enter the file name that you want to add to the list of default documents and then click **OK**. This file name is added to the top of the default document list.
4. Optionally, select a default document in the list and in the **Actions** pane, click **Move Up** or **Move Down** to change the file's precedence.
5. Optionally, select a default document in the list, and in the **Actions** pane, click **Remove** to remove any file names that you do not want to use as default documents.

To configure the default document by using the command line

- To add a file name to the list of default documents, use the following syntax:

  ```
  appcmd set config /section:defaultDocument /+files.[value='string']
  ```

  The variable `string` is the file name that you want to add to the list. For example, to add a file named **home.html** to the default document list, enter the following at the command prompt:

  ```
  appcmd set config /section:defaultDocument /+files.[value='home.html']
  ```

  To remove a file named **home.html** from the default document list, enter the following at the command prompt, and then press ENTER:

  ```
  appcmd set config /section:defaultDocument /-files.[value='home.html']
  ```

Step 5: Configure Static Content Compression

You can optionally configure your web server to compress static content to user bandwidth more efficiently and to enhance the performance of your website.

To configure static content compression by using the UI

1. In **Features View** of IIS Manager, double-click **Compression**.
2. Select **Enable static content compression** to configure IIS to compress static content.
3. In the **Static Compression** box, configure the following settings:
   a. Optionally, select **Only compress files larger than (in bytes)** and enter the minimum file size that you want IIS to compress. The default size is 256 bytes.
   b. In the **Cache directory** text box, enter the path of a local directory or click the browse button (**…**) to locate a directory. After a static file is compressed, it is cached in this

temporary directory until it expires, or until the content changes. The temporary directory must be on a local drive on an NTFS-formatted partition. The directory cannot be compressed, and should not be shared.

c. Optionally, select **Per application pool disk space limit (in MB)** and enter the maximum amount of space per application pool, in megabytes, you want IIS to use when it compresses static content. For example, if there are 20 application pools on the server and the **Disk space limit** is set to 100, the maximum disk space will be 2GB. If you click the **Per application pool disk space limit (in MB)** option and enter a number in the text box under it, IIS automatically cleans up the temporary directory according to a least recently used rule when the set limit is reached. The default is 100 MB per application pool.

4. Click **Apply** in the **Actions** pane.

To configure static content compression by using the command line

- To enable HTTP compression of static content, at the command prompt, enter the following command, and then press Enter:

  ```
  appcmd set config /section:urlCompression /doStaticCompression:True
  ```

- To configure static-content compression settings, use the following syntax:

  ```
  appcmd set config /section:urlCompression /minFileSizeforComp:int /directory:string
  /maxDiskSpace:int
  ```

  The variable `minFileSizeforComp` sets the minimum number of bytes that a file must contain for it to be compressed. The default value is 256. The variable `directory` specifies the directory where compressed versions of static files are temporarily stored and cached. The default is the following folder:

  `%SystemDrive%\inetpub\temp\IIS Temporary Compressed Files`

  The variable `maxDiskSpace` sets the maximum amount of space per application pool, in megabytes, that you want IIS to use when it compresses static content. The default is 100 MB per application pool.

Next Steps

Test your website thoroughly to ensure that it functions as expected. Then consider configuring the following features.

- To help you troubleshoot or optimize the performance of your web server, set up IIS logging. For instructions see, Configure Logging in IIS.
- To improve the security of your web server, configure request filtering. For instructions see, Configure Request Filtering in IIS.

Configure Request Filtering in IIS

This document shows you how to use common request-filter settings to improve the security of your IIS 8 web server.

Request filters restrict the types of HTTP requests that IIS 8 processes. By blocking specific HTTP requests, request filters help prevent potentially harmful requests from reaching the server. The request filter module scans incoming requests and rejects requests that are unwanted based upon the rules that you set up.

By default, IIS rejects requests to browse critical code segments. It also rejects requests for some file name extensions.

You can configure a request filter at the server-wide level and then override the configuration at a website level.

- Prerequisites
- General Request Filter Settings
- File Name Extensions
- Filtering Rules
- Hidden Segments
- URL Filtering
- HTTP Verbs
- Header Size Limits
- Query Strings
- Request Filter Logging

Prerequisites

This guide was written for, and tested on, the following operating systems:

- Windows Server® 2012
- Windows® 8

General Request Filter Settings

The general settings include such settings as the following:

1. Whether to allow access to a file with an extension that is not listed for request filter.
2. Whether to allow requests that use HTTP verbs that are not listed.

3. Whether to allow requests that contain high-bit characters (non-ASCII).
4. Whether to allow requests that are double encoded.
5. Maximum length of the content requested.
6. Maximum length of the URL
7. Maximum size of a query string

To configure general request-filter options by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. In the **Actions** pane, click **Edit Feature Settings**.
4. In the **Edit Request Filtering Settings** dialog, edit the settings as desired, and then click **OK**.

To configure general request-filter options by using the command line

- To configure high-bit characters, use the following syntax:

  appcmd set config /section:requestfiltering /allowhighbitcharacters:true | false

  For example, to allow high-bit characters, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /allowhighbitcharacters:true
- To configure double escaping, use the following syntax:

  appcmd set config /section:requestfiltering /allowdoubleescaping:true | false

  For example, to enable double escaping, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /allowdoubleescaping:true
- To configure a value for the maximum allowed length of content, use the following syntax:

  appcmd set config /section:requestfiltering /requestlimits.maxallowedcontentlength:*unit*

  The variable **requestlimits.maxallowedcontentlength** *unit* specifies the maximum length of content.

  For example, to specify 30000000 as the maximum length of content, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /requestlimits.maxallowedcontentlength:30000000
- To configure a value for the maximum allowed length of an incoming URL, use the following syntax:

  appcmd set config /section:requestfiltering /requestlimits.maxurl:*unit*

  The variable **requestlimits.maxurl** *unit* specifies the maximum length of an incoming URL.

For example, to specify 4096 as the maximum incoming URL length, type the following at the command prompt, and then press ENTER:

appcmd set config /section:requestfiltering /requestlimits.maxurl:4096

- To configure a value for the maximum allowed length of an incoming query string, use the following syntax:

  appcmd set config /section:requestfiltering /requestlimits.maxquerystring:*unit*

  The variable **requestlimits.maxquertystring** *unit* specifies the maximum length of an incoming query string.

  For example, to specify 2048 as the maximum incoming query string, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /requestlimits.maxquerystring:2048

- To configure a size limit for a specific HTTP header, use the following syntax:

  appcmd set config /section:requestfiltering /+requestlimits.headerLimits.[header='*string***',sizelimit='***unit***']**

  The variable **header** *string* specifies the header this restriction applies to. The variable **sizelimit** *unit* specifies the maximum size of this header.

  For example, to specify a maximum size of 2048 for headers that include a value of contoso.com, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /+requestlimits.headerLimits.[header='contoso.com',sizelimit='2048']

File Name Extensions

For each file name extension you add, you can indicate whether to allow or reject requests for that type of file.

To configure file name extensions by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **File Name Extensions** tab.
4. In the **Actions** pane, click either **Allow File Name Extension** or **Deny File Name Extension**.
5. Type the file name extension in the box, and then click **OK**.

To configure file name extensions by using the command line

- To configure how IIS deals with unlisted file name extensions, use the following syntax:

  appcmd set config /section:requestfiltering /fileExtensions.allowunlisted:true | false

  For example, to deny unlisted file name extensions, type the following at the command

prompt, and then press ENTER:

appcmd set config /section:requestfiltering /fileExtensions.allowunlisted:false

- To configure whether file name extensions apply to WebDAV requests, use the following syntax:

  appcmd set config /section:requestfiltering /fileExtensions.applyToWebDAV:true | false

  For example, to configure IIS so that file name extensions do not apply to WebDAV requests, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /fileExtensions.applyToWebDAV:false

- To add a file name extension, use the following syntax:

  appcmd set config /section:requestfiltering /+fileExtensions.[fileextension='*.string***',allowed='true | false']**

  The variable **fileextension** *string* is the file name extension you want to allow or deny.

  For example, to add an allow rule for the file name extension .xxx, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /+fileExtensions.[fileextension='*.xxx***',allowed='true']**

- To remove a rule for the file name extension .xxx, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /-fileExtensions.[fileextension='*.xxx***']**

Filtering Rules

IIS 8 permits you to define custom filter rules that apply to incoming requests. Using this feature, you can define filters that can do the following:

1. Scan the request URL.
2. Scan for query strings contained in the URL.
3. Scan for specific header fields.
4. Define what file name extensions the filter applies to.
5. Define strings you want to deny.

To configure a filtering rule by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **Rules** tab.
4. In the **Actions** pane, double-click **Add Filtering Rule**.
5. In the **Name** box, type a name for the filtering rule.
6. If you want the URL scanned, select the **Scan Url** check box.
7. If you want the query string scanned, select the **Scan query string** check box.

8. Under **Scan Headers**, type one or more headers to scan for.
9. Under **Applies To**, type one or more file name extensions that the rule applies to.
10. Under the **Deny Strings**, type one or more strings you want to deny.
11. Click **OK**.

Hidden Segments

This feature allows you to reject requests that contain a URL segment (for example, a folder name).

To configure hidden segments by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **Hidden Segments** tab.
4. In the **Actions** pane, click **Add Hidden Segment**.
5. Type the URL segment in the box, and then click **OK**.

To configure hidden segments by using the command line

- To configure whether hidden segments apply to WebDAV requests, use the following syntax:

  appcmd set config /section:requestfiltering /hiddensegments.applyToWebDAV:true | false

  For example, to configure IIS so that hidden segments do not apply to WebDAV requests, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /hiddensegments.applyToWebDAV:false
- To configure a hidden segment, use the following syntax:

  appcmd set config /section:requestfiltering /+hiddensegments.[segment='*string***']**

  The variable **segment** *string* specifies a URL segment that is hidden.

  For example, to specify that /bin is a hidden segment, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /+hiddensegments.[segment='/bin']

URL Filtering

You can configure IIS to accept a specified URL. In addition, you can configure it to deny a specified URL sequence.

To configure URL filtering by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **URL** tab.
4. In the **Actions** pane, select either **Allow URL** or **Deny Sequence**.
5. Type the URL or the URL sequence in the box, and click **OK**.

To configure URL filtering by using the command line

- To deny a URL sequence, use the following syntax:

  appcmd set config /section:requestfiltering /+denyurlsequences.[sequence='*string***']**

  The variable **sequence** *string* specifies a sequence of characters in a URL that IIS is never allowed to parse.

  For example, to specify that IIS never parse URLs that contain two periods, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /+denyurlsequences.[sequence='..']

HTTP Verbs

You can define a list of verbs that IIS 8 accepts as part of a request. When IIS rejects a request based on this feature, the error code logged is 404.6.

To configure unlisted HTTP verbs by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **HTTP Verbs** tab.
4. In the **Actions** pane, click either **Allow Verb** or **Deny Verb**.
5. Enter the verb in the box, and then click **OK**.

To configure unlisted HTTP verbs by using the command line

- To configure how IIS deals with unlisted verbs, use the following syntax:

  appcmd set config /section:requestfiltering /verbs.allowunlisted:true | false

  For example, to deny unlisted verbs, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /verbs.allowunlisted:false
- To configure whether verb filtering applies to WebDAV requests, use the following syntax:

  appcmd set config /section:requestfiltering /verbs.applyToWebDAV:true | false

  For example, to configure IIS so that verb filtering does not apply to WebDAV requests, type the following at the command prompt and then press ENTER:

appcmd set config /section:requestfiltering /verbs.applyToWebDAV:false

- To configure a verb to filter, use the following syntax:

  appcmd set config /section:requestfiltering /+verbs.[verb='*string***',allowed='true | false']**

  The variable **verb** *string* specifies the verb this restriction applies to.

  For example, to specify GET is allowed, type the following at the command prompt, and then press ENTER:

  appcmd set config /section:requestfiltering /+verbs.[verb='GET',allowed='true']

Header Size Limits

You can limit the size of HTTP request headers to improve performance and security. Headers are name/value pairs that define the operating parameters of an HTTP transaction.

To configure header size limits by using the UI

1. Open IIS Manager and select the level for which you want to configure request filter.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **Headers** tab, and click **Add Header**.
4. In the **Header** box, type the header field name.
5. In the **Size Limit** box, type a positive integer that represents the header size limit in bytes.
6. Click **OK**.

Query Strings

You can configure IIS 8 to allow or deny specific query strings contained in the requested URL. For example, if a denied query string is found in a request URL, the request is denied.

To configure query strings by using the UI

1. Open IIS Manager and select the level you want to configure request filter for.
2. In **Features View**, double-click **Request Filtering**.
3. Select the **Query Strings** tab, and click either **Allow Query String** or **Deny Query String**.
4. In the **Query string** box, type the query string.
5. Click **OK**.

Request Filter Logging

You can use IIS logging to evaluate and optimize your request filter configuration.

The following table shows the request filter error codes that you see in the log:

Error Description	Status Code
Request Filtering: URL Sequence denied	404.5
Request Filtering: Verb denied	404.6
Request Filtering: File name extension denied	404.7
Request Filtering: Denied by hidden segment	404.8
Request Filtering: Denied because request header is too long.	404.10
Request Filtering: Denied because URL doubled escaping	404.11
Request Filtering: Denied because of high bit characters	404.12
Request Filtering: Denied because content length too large	404.13
Request Filtering: Denied because URL too long	404.14
Request Filtering: Denied because query string too long	404.15

Configure Logging in IIS

You can configure logging on your web server or website that records information about HTTP requests and errors. The information in your log can help you troubleshoot or optimize your website.

Choose one or more of the following procedures to set up logging appropriately for your needs:

- Prerequisites
- Configure Logging at the Site Level
- Configure Per-site Logging at the Server Level
- Configure Per-server Logging at the Server Level
- Select W3C Fields to Log
- Configure Log File Rollover Options

Prerequisites

This guide was written for, and tested on, the following operating systems:

- Windows Server® 2012 R2
- Windows Server® 2012
- Windows® 8

Configure Logging at the Site Level

You can perform this procedure by using the user interface (UI), or by editing configuration files directly.

To configure logging at the site level by using the UI

1. Open IIS Manager.
   - For Windows Server 2012, on the **Start** page click the **Server Manager** tile, and then click **OK**. In **Server Manager**, click the **Tools** menu, and then click **Internet Information Services (IIS) Manager**.
   - For Windows 8, on the **Start** page type **Control Panel**, and then click the **Control Panel** icon in the search results. On the **Control Panel** screen, click **System and Security**, click **Administrative Tools**, and then **click Internet Information Services (IIS) Manager**.
2. In the **Connections** tree view, select your website.
3. In **Features View**, double-click **Logging**.
4. On the **Logging** page, in the **Log file** section under **Format**, select one of the following log file formats:
   - **IIS**: to use the Microsoft IIS log file format to log information about a site. This format is handled by HTTP.sys, and is a *fixed* ASCII text-based format, which means that you cannot customize the fields that are logged. Fields are separated by commas, and time is recorded as local time. For more information about the IIS log file format, see IIS Log File Format (IIS 6.0).
   - **NCSA**: to use the National Center for Supercomputing Applications (NCSA) Common log file format to log information about a site. This format is handled by HTTP.sys, and is a *fixed* ASCII text-based format, which means that you cannot customize the fields that are logged. Fields are separated by spaces, and time is recorded as local

time with the Coordinated Universal Time (UTC) offset. For more information about the NCSA log file format, see NCSA Common Log File Format (IIS 6.0).

- **W3C**: to use the centralized W3C log file format to log information about all sites on the server. This format is handled by HTTP.sys, and is a *customizable* ASCII text-based format, which means that you specify the fields that are logged. Specify the fields that are logged on the **W3C Logging Fields** dialog box by clicking **Select Fields** on the **Logging** page. Fields are separated by spaces, and time is recorded in Coordinated Universal Time (UTC). For more information about the W3C log file format, see W3C Extended Log File Format (IIS 6.0).

  Note
  In Windows Server 2012 R2 and later, you can write log information to a log file, as Event Tracing for Windows (ETW) events, or both. For more information on ETW, see Event Tracing.

- **Custom**: to use a custom format for a custom logging module. When you select this option, the **Logging** page becomes disabled, because custom logging cannot be configured in IIS Manager. For more information about how to use custom log file formats, see Custom Logging Modules (IIS 6.0).

5. Under **Directory**, specify the path where the log file should be stored. The default is *%SystemDrive%*\inetpub\logs\LogFiles

   Note
   As a best practice, store log files, such as failed request trace logs, in a directory other than *systemroot*.

6. In the **Log File Rollover** section, select one of the following options:
   - **Schedule**: to create new log file that is based on one of the following values:
   - **Hourly**: a new log file is created each hour.
   - **Daily**: a new log file is created each day.
   - **Weekly**: a new log file is created each week.
   - **Monthly**: a new log file is created each month.
   - **Maximum file size (in bytes)**: to create a log file when the file reaches a certain size (in bytes).The minimum file size is 1048576 bytes. If this attribute is set to a value less than 1048576 bytes, the default value is implicitly assumed as 1048576 bytes.
   - **Do not create a new log file**: there is a single log file that continues to grow as information is logged.
7. Select **Use local time for file naming and rollover** to specify that log file naming and time for log file rollover uses the local server time. When this option is not selected, Coordinated Universal Time (UTC) is used.

   Note
   Regardless of this setting, timestamps in the actual log file will use the time format for the log format that you select from the **Format** list. For example, NCSA and W3C log file formats use UTC time format for timestamps.

8. Click **Apply** in the **Actions** pane.

Configure Per-site Logging at the Server Level

You can perform this procedure by using the user interface (UI), or by editing configuration files directly.

To configure per-site logging at the server level by using the UI

1. In the **Connections** tree view of IIS Manager, select your web server.
2. In **Features View**, double-click **Logging**.
3. On the **Logging** page under **One log file per site**, select **Site** from the drop-down list. By default, **Site** is selected.
4. Complete this procedure by following the site-level procedure by starting with step 4.

Configure Per-server Logging at the Server Level

You can perform this procedure by using the user interface (UI), or by editing configuration files directly.

To configure per-server logging at the server level by using the UI

1. In the **Connections** tree view of IIS Manager, select your web server.
2. In **Features View**, double-click **Logging**.
3. On the **Logging** page, under **One log file per site**, select **Server** from the drop-down list. By default, **Site** is selected.
4. Complete this procedure by following the site-level procedure by starting with step 4.

Select W3C Fields to Log

You can perform this procedure by using the user interface (UI), or by editing configuration files directly.

To select W3C fields to log by using the UI

1. In **Features View** of IIS Manager, double-click **Logging**.
2. On the **Logging** page, in the **Log file** section under **Format**, click **Select Fields**.
3. In the **W3C Logging Fields** dialog box, select one or more of the following options:
   - **Date (date)**: the date on which the request occurred.
   - **Time (time)**: the time, in Coordinated Universal Time (UTC), at which the request occurred.
   - **Client IP Address (c-ip)**: the IP address of the client that made the request.
   - **User Name (cs-username)**: the name of the authenticated user who accessed your

server. Anonymous users are indicated by a hyphen.

- **Service Name (s-sitename)**: the site instance number that fulfilled the request.
- **Server Name (s-computername)**: the name of the server on which the log file entry was generated.
- **Server IP Address (s-ip)**: the IP address of the server on which the log file entry was generated.
- **Server Port (s-port)**: the server port number that is configured for the service.
- **Method (cs-method)**: the requested action, for example, a GET method.
- **URI Stem (cs-uri-stem)**: the Universal Resource Identifier, or target, of the action.
- **URI Query (cs-uri-query)**: the query, if any, that the client was trying to perform. A Universal Resource Identifier (URI) query is necessary only for dynamic pages.
- **Protocol Status (sc-status)**: the HTTP or FTP status code.
- **Protocol Sub-status (sc-substatus)**: the HTTP or FTP substatus code.
- **Win32 Status (sc-win32-status)**: the Windows status code.
- **Bytes Sent (sc-bytes)**: the number of bytes that the server sent.
- **Bytes Received (cs-bytes)**: the number of bytes that the server received.
- **Time Taken (time-taken)**: the length of time that the action took in milliseconds.
- **Protocol Version (cs-version)**: the protocol version, HTTP or FTP, that the client used.
- **Host (cs-host)**: the host name, if any.
- **User Agent (cs(UserAgent))**: the browser type that the client used.
- **Cookie (cs(Cookie))**: the content of the cookie sent or received, if any.
- **Referer (cs(Referer))**: the site that the user last visited. This site provided a link to the current site.

Note
In Windows Server 2012 R2 and later, you can specify additional custom fields to log from the HTTP request and response headers, and from server variables. To add custom fields, select **Add Field** in the **W3C Logging Fields** dialog box. Enhanced logging is available only for site-level logging - if you selected server-level logging, then **Add Field** is disabled. Note that if the total size of the custom fields that you define is greater than 64K bytes, the logged content is truncated to 64K bytes.

4. Click **Apply** in the **Actions** pane.

Configure Log File Rollover Options

You can perform this procedure by using the user interface (UI), or by editing configuration files directly.

To configure log file rollover options by using the UI

1. In **Features View** of IIS Manager, double-click **Logging**.
2. On the **Logging** page, in the **Log File Rollover** section, select one of the following options:
   - **Schedule**: to create new log file that is based on one of the following values:
   - **Hourly**: a new log file is created each hour.
   - **Daily**: a new log file is created each day.
   - **Weekly**: a new log file is created each week.
   - **Monthly**: a new log file is created each month.
   - **Maximum file size (in bytes)**: to create a log file when the file reaches a certain size (in bytes).The minimum file size is 1048576 bytes. If this attribute is set to a value less than 1048576 bytes, the default value is implicitly assumed as 1048576 bytes.
   - **Do not create a new log file**: This option means that there is a single log file that continues to grow as information is logged. If you use a single log file for your site, it is helpful when you use log parsing utilities, but it also creates larger log files that could affect the overall performance of the server.
3. Select **Use local time for file naming and rollover** to specify that log file naming and time for log file rollover uses the local server time. When this option is not selected, Coordinated Universal Time (UTC) is used.

   Note
   Regardless of this setting, timestamps in the actual log file will use the time format for the log format that you select from the **Format** list. For example, NCSA and W3C log file formats use UTC time format for timestamps.
4. Click **Apply** in the **Actions** pane.

Build a Classic ASP Website on IIS

This document guides you through installing IIS and configuring a classic ASP website. Classic ASP is a server-side scripting environment that you can use to create and run dynamic web applications. With ASP, you can combine HTML pages, script commands, and COM components

to create interactive web pages that are easy to develop and modify. Classic ASP is the predecessor to ASP.NET, but it is still in wide use today.

The Classic ASP server configuration adds IIS modules for ASP and ISAPI extensions to the default IIS installation.

In this document

- Prerequisites
- Step 1: Install the IIS Web Server
- Step 2: Add a Classic ASP Website
- Step 3: Edit ASP Application Settings
- Next Steps

Prerequisites

This guide was written for, and tested on, the following operating systems:

1. Windows Server® 2012
2. Windows® 8

Step 1: Install the IIS Web Server

You can use the Web Platform Installer (Web PI) to install IIS, and applications that run on IIS. Because the Web PI installs the latest versions of available Web Platform offerings, with just a few simple clicks you can download and install any new tools or updates. To learn more about the Web PI, see Learn more and install the Web PI.

You can also perform this procedure by using the Windows user interface (UI) or from a command line.

To install IIS on Windows Server 2012 by using the UI

1. On the **Start** page, click the **Server Manager** tile, and then click **OK**.
2. In **Server Manager**, select **Dashboard**, and click **Add roles and features**.
3. In the **Add Roles and Features Wizard**, on the **Before You Begin** page, click **Next**.
4. On the **Select Installation Type** page, select **Role-based or Feature-based Installation** and click **Next**
5. On the **Select Destination Server** page, select **Select a server from the server pool**, select your server, and click **Next**.
6. On the **Select Server Roles** page, select **Web Server (IIS)**, and then click **Next**.
7. On the **Select Features** page, note the preselected features that are installed by default, and then select the following additional role services:
   - ASP
   - ISAPI Extensions
8. Click **Next**.

9. On the **Web Server Role (IIS)** page, click **Next**.
10. On the **Select Role Services** page, note the preselected role services that are installed by default, and then click **Next**.

    Note
    You only have to install the IIS 8 default role services for a static-content web server.
11. On the **Confirm Installation Selections** page, confirm your selections, and then click **Install**.
12. On the **Installation Progress** page, confirm that your installation of the Web Server (IIS) role and required role services completed successfully, and then click **Close**.
13. To verify that IIS installed successfully, type the following into a web browser:

    http://localhost

    You should see the default IIS Welcome page.

To install IIS on Windows 8 by using the UI

1. On the **Start** page, type **Control Panel**, and then click the **Control Panel** icon in the search results.
2. In **Control Panel**, click **Programs**, and then click **Turn Windows features on or off**.
3. In the **Windows Features** dialog box, click **Internet Information Services**, note the preselected features that are installed by default, and then select the following additional role services:
   - ASP
   - ISAPI Extensions
4. Click **OK**.
5. To verify that IIS installed successfully, type the following into a web browser:

   http://localhost

   You see the default IIS Welcome page.

To Install IIS by using the command line

- Type the following command at a command prompt or into a script:

  Start /w pkgmgr /iu:IIS-WebServerRole;IIS-WebServer;IIS-CommonHttpFeatures;IIS-StaticContent;IIS-DefaultDocument;IIS-DirectoryBrowsing;IIS-HttpErrors;IIS-ApplicationDevelopment;IIS-ASP;IIS-ISAPIExtensions;IIS-HealthAndDiagnostics;IIS-HttpLogging;IIS-LoggingLibraries;IIS-RequestMonitor;IIS-Security;IIS-RequestFiltering;IIS-HttpCompressionStatic;IIS-WebServerManagementTools;IIS-ManagementConsole;WAS-WindowsActivationService;WAS-ProcessModel;WAS-NetFxEnvironment;WAS-ConfigurationAPI

Step 2: Add a Classic ASP Website

You can perform this procedure by using the user interface (UI), by running Appcmd.exe commands in a command-line window, by editing configuration files directly, or by writing WMI scripts.

To add a website by using the UI

1. Open IIS Manager.
   - For Windows Server 2012, on the **Start** page click the **Server Manager** tile, and then click **OK**. On the **Server Manager Dashboard**, click the **Tools** menu, and then click **Internet Information Services (IIS) Manager**.
   - For Windows 8, on the **Start** page type **Control Panel**, and then click the **Control Panel** icon in the search results. On the **Control Panel** screen, click **System and Security**, click **Administrative Tools**, and then **click Internet Information Services (IIS) Manager**.
2. In the **Connections** pane, right-click the **Sites** node in the tree, and then click **Add Website**.
3. In the **Add Website** dialog box, type a friendly name for your website in the **Site name** box.
4. If you want to select a different application pool than the one listed in the **Application Pool** box, click **Select**. In the **Select Application Pool** dialog box, select an application pool from the **Application Pool** list and then click **OK**.
5. In the **Physical path** box, type the physical path of the Web site's folder, or click the browse button (**...**) to navigate the file system to find the folder.
6. If the physical path that you entered in step 5 is to a remote share, click **Connect as** to specify credentials that have permission to access the path. If you do not use specific credentials, select the **Application user (pass-through authentication)** option in the **Connect As** dialog box.
7. Select the protocol for the Web site from the **Type** list.
8. The default value in the **IP address** box is **All Unassigned**. If you must specify a static IP address for the Web site, type the IP address in the **IP address** box.
9. Type a port number in the **Port** text box.
10. Optionally, type a host header name for the Web site in the **Host Header** box.
11. If you do not have to make any changes to the site, and you want the Web site to be immediately available, select the **Start Web site immediately** check box.
12. Click **OK**.

To add a website by using the command line

- Use the following syntax at the command prompt or in a script:

  Note
  For this syntax to work, you either must be in the following directory, or have the

directory in your path: `%windir%\system32\inetsrv`

appcmd add site /name:*string* **/id:***uint* **/physicalPath:***string* **/bindings:***string*

The variable **name** *string* is the name, and the variable **id** *uint* is the unsigned integer that you want to assign to the site. The variables **name** *string* and **id** *uint* are the only variables that are required when you add a site in Appcmd.exe.

Note

When you add a site without specifying the values for the **bindings** and **physicalPath** attributes, the site will not be able to start.

The variable **physicalPath** *string* is the path of the site content in the file system.

The variable **bindings** *string* contains information that is used to access the site, and it should be in the form of *protocol*/*IP_address*:*port*:*host_header*. For example, a web site binding is the combination of protocol, IP address, port, and host header. A binding of **http/*:85:** enables a web site to listen for HTTP requests on port 85 for all IP addresses and domain names (also known as host headers or host names). On the other hand, a binding of **http/*:85:marketing.contoso.com** enables a web site to listen for HTTP requests on port 85 for all IP addresses and the domain name **marketing.contoso.com**.

To add a web site named **contoso** with an ID of 2 that has content in **c:\contoso**, and that listens for HTTP requests on port 85 for all IP addresses and a domain name of **marketing.contoso.com**, type the following at the command prompt, and then press ENTER:

appcmd add site /name:contoso /id:2 /physicalPath:c:\contoso /bindings:http/*:85:marketing.contoso.com

Step 3: Edit ASP Application Settings

IIS 8 provides default settings for ASP applications, but you can change those settings as needed. For example, you can enable client-side debugging on a test server to aide in troubleshooting issues during a test pass.

To edit ASP application settings by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **ASP**.
3. On the **ASP** page, edit settings as desired.
4. When finished, click **Apply** in the **Actions** pane.

To edit ASP application settings by using the command line

- **Specify default character set**

  To specify the default character set for an application, use the following syntax:

  appcmd set config /section:asp /codePage:*integerRange*

The variable *integerRange* is the default character set. For example, to set the code page to a Latin character set used in American English and many European alphabets, type the following at the command prompt, and then press Enter:

appcmd set config /section:asp /codePage:*1252*

- **Enable or disable buffering**

  To enable or disable buffering of ASP application output, use the following syntax:

  appcmd set config /section:asp /bufferingOn:True|False

  True enables buffering whereas **False** disables buffering. The default value is **True**.

- **Enable or disable HTTP 1.1 chunked transfer encoding**

  To enable HTTP 1.1 chunked transfer encoding for the World Wide Web publishing service, use the following syntax:

  appcmd set config /section:asp /enableChunkedEncoding:True|False

  True enables HTTP 1.1 chunked transfer encoding whereas **False** disables HTTP 1.1 chunked transfer encoding. The default value is **True**.

- **Enable or disable HTML fallback**

  To enable or disable HTML fallback, use the following syntax:

  appcmd set config /section:asp /enableASPHTMLFallback:True|False

  True causes an .htm file that has the same name as the requested .asp file, if it exists, to be sent instead of the .asp file if the request is rejected because of a full request queue. The default value is **True**.

- **Enable or disable parent paths**

  To enable or disable paths relative to the current directory or above the current directory, use the following syntax:

  appcmd set config /section:asp /enableParentPaths:True|False

  True sets ASP pages to allow paths relative to the current directory or above the current directory. The default value is **True**.

- **Set client connection test interval**

  To set a time interval after which ASP will check to see whether the client is still connected before executing a request, use the following syntax:

  appcmd set config /section:asp /queueConnectionTestTime:*timeSpan*

  The variable *timeSpan* sets the time interval (hh:mm:ss) after which ASP checks to see whether the client is still connected before executing a request. The default value is 00:00:03.

- **Set maximum requesting entity body limit**

  To specify the maximum number of bytes allowed in the entity body of an ASP request, use the following syntax:

  appcmd set config /section:asp /maxRequestEntityAllowed:*int*

  The variable *int* represents the maximum number of bytes allowed in the body of an ASP

request. The default value is 200000 bytes.

- **Set request queue length**

  To specify the maximum number of concurrent ASP requests allowed into the queue, use the following syntax:

  appcmd set config /section:asp /requestQueueMax:*int*

  The variable *int* represents the maximum number of concurrent ASP requests that are allowed into the request queue. The default value is 3000.

- **Set request queue time-out**

  To specify the period that an ASP request can wait in the request queue, use the following syntax:

  appcmd set config /section:asp /queueTimeout:*timeSpan*

  The variable *timeSpan* represents the maximum time (hh:mm:ss) that an ASP request can wait in the request queue. The default value is 00:00:00.

- **Specify response buffering limit**

  To control the maximum number of bytes that an ASP page can write to the response buffer before a flush occurs, use the following syntax:

  appcmd set config /section:asp /bufferingLimit:*int*

  The variable *int* represents the maximum size, in bytes, of the ASP buffer. The default value is 4194304 bytes.

- **Set script time-out**

  To specify the default length of time that ASP pages let a script run before terminating the script and writing an event to the Windows Event Log, use the following syntax:

  appcmd set config /section:asp /scriptTimeout:*timeSpan*

  The variable *timeSpan* represents the maximum time (hh:mm:ss) that an ASP request can run before an event is written to the Windows Event Log. The default value is 00:01:30.

- **Specify threads per processor limit**

  To specify the maximum number of worker threads per processor that ASP can create, use the following syntax:

  appcmd set config /section:asp /processorThreadMax:*int*

  The variable *int* represents the maximum number of worker threads per processor that ASP can create. The default value is 25.

- **Specify default locale identifier**

  To define how dates, times, and currencies are formatted for an ASP application, use the following syntax:

  appcmd set config /section:asp /lcid:*int*

  The variable *int* represents the default locale identifier for an ASP application. The default value is 0.

- **Enable or disable automatic application restart**

  To enable or disable automatic restart of ASP applications whenever a configuration setting is changed, use the following syntax:

  appcmd set config /section:asp /enableApplicationRestart:True|False

  True enables ASP applications to be automatically restarted whenever a configuration setting is changed. The default value is **True**.
- **Enable or disable line number calculation**

  To enable or disable ASP to calculate and store the line number of each executed line of code to provide the number in an error report, use the following syntax:

  appcmd set config /section:asp /calLineNumber:True|False

  True enables line number calculation and storage. The default value is **True**.
- **Enable or disable COM component exception trapping**

  To enable or disable ASP pages to catch exceptions thrown by COM components, use the following syntax:

  appcmd set config /section:asp /exceptionCatchEnable:True|False

  True enables COM component exception trapping. If set to **False**, the Microsoft Script Debugger tool does not catch exceptions sent by the component that you are debugging. The default value is **True**.
- **Enable or disable client-side debugging**

  To enable or disable client-side debugging, use the following syntax:

  appcmd set config /section:asp /appAllowClientDebug:True|False

  True enables client-side debugging. The default value is **False**.
- **Enable or disable log error requests**

  To enable or disable the writing of ASP errors to the application section of the Windows event log, use the following syntax:

  appcmd set config /section:asp /logErrorRequests:True|False

  True enables log error requests. By default, ASP errors are written to the client browser and the IIS logs. The default value is **True**.
- **Enable or disable server-side debugging**

- **Enable or disable Windows event logging of ASP errors**

  To enable or disable ASP debugging on the server, use the following syntax:

  appcmd set config /section:asp /appAllowDebugging:True|False

  True enables server-side debugging for ASP applications. The default value is **False**.
- **Run On End Functions Anonymously**

  To enable or disable **SessionOnEnd** and **ApplicationOnEnd** global ASP functions to run as the anonymous user, use the following syntax:

  appcmd set config /section:asp /runOnEndAnonymously:True|False

True enables **SessionOnEnd** and **ApplicationOnEnd** global ASP functions to run as the anonymous user. The default value is **True**.

- **Specify script error message**

  To specify the error message to send to the browser if specific debugging errors are not sent to the client, use the following syntax:

  appcmd set config /section:asp /scriptErrorMessage:*string*

  The variable *string* represents the error message that is sent to the browser when specific debugging errors are not sent to the client. The default value is "An error occurred on the server when processing the URL. Please contact the system administrator".

- **Enable or disable sending errors to the browser**

  To enable or disable the writing of debugging specifics (file name, error, line number, and description) to the client browser in addition to logging them to the Windows event log, use the following syntax:

  appcmd set config /section:asp /scriptErrorSentToBrowser:True|False

  True enables the writing of debugging specifics to the client browser. The default value is **False**.

- **Specify default script language**

  To specify the default script language for all ASP applications that are running on the web server, use the following syntax:

  appcmd set config /section:asp /scriptLanguage:*string*

  The variable *string* represents the default script language. The default value is VBScript.

- **Specify cache directory path**

  To specify the name of the directory where ASP stores compiled ASP templates when the in-memory cache overflows, use the following syntax:

  appcmd set config /section:asp /diskTemplateCacheDirectory:*string*

  The variable *string* represents the cache directory path. The default value is *%windir%*\system32\inetsrv\ASP Compiled Templates.

- **Enable or disable type library caching**

  To enable or disable the caching of type libraries, use the following syntax:

  appcmd set config /section:asp /enableTypelibCache:True|False

  True enables the caching of type libraries. The default value is **True**.

- **Set maximum number of compiled ASP templates to store**

  To set the maximum number of compiled ASP templates that can be stored, use the following syntax:

  appcmd set config /section:asp /maxDiskTemplateCacheFiles:*int*

  The variable *int* represents the maximum number of compiled ASP templates to store. The default value is 2000.

- **Set maximum number of compiled ASP templates to store**

  To set the maximum number of precompiled script files to cache, use the following syntax:

  appcmd set config /section:asp /scriptFileCacheSize:*int*

  The variable *int* represents the number of precompiled script files to cache. If set to 0, no script files are cached. If set to 4294967295, all requested script files are cached. The default value is 500.

- **Set maximum number of scripting engines to cache**

  To set the maximum number of scripting engines that ASP pages keep cached in memory, use the following syntax:

  appcmd set config /section:asp /scriptEngineCacheMax:*int*

  The variable *int* represents the maximum number of scripting engines that are cached. The default value is 250.

- **Enable or disable COM+ side-by-side assemblies**

  To enable or disable side-by-side COM+ assemblies, which allow ASP applications to specify which version of a system DLL or classic COM component to use, use the following syntax:

  appcmd set config /section:asp /appServiceFlags:True|False

  True enables COM+ side-by-side assemblies. The default value is **False**.

- **Enable or disable COM+ tracker**

  To enable or disable COM+ tracker, use the following syntax:

  appcmd set config /section:asp /enableTypelibCache:True|False

  True enables COM+ tracker, which lets administrators or developers debug ASP applications. The default value is **False**.

- **Enable or disable multithreaded environments**

  To enable or disable ASP to run in a multithreaded environment, use the following syntax:

  appcmd set config /section:asp /executeInMta:True|False

  True enables ASP to run in a multithreaded environment. The default value is **False**.

- **Enable or disable thread model checking**

  To enable or disable whether IIS checks the threading model of any component that your application creates, use the following syntax:

  appcmd set config /section:asp /trackThreadingModel:True|False

  True enables thread model checking. The default value is **False**.

- **Specify COM+ partition ID**

  To specify the Globally Unique Identifier (GUID) of the COM+ partition, use the following syntax:

  appcmd set config /section:asp /partitionID:*string*

The variable *string* represents the GUID of the COM+ partition. The default value is 00000000-0000-0000-0000-000000000000.

Note
You must also set the **appServiceFlags** flag to **True**.

- **Specify COM+ application**

  To specify the name of the COM+ application, use the following syntax:

  appcmd set config /section:asp /sxsName:*string*

  The variable *string* represents name of the COM+ application.

  Note
  You must also set the **appSeviceFlags** flag to **True**.

- **Enable or disable COM+ partitioning**

  To enable or disable COM+ partitioning, use the following syntax:

  appcmd set config /section:asp /appServiceFlags:True|False

  True enables COM+ partitioning, which can be used to isolate applications in their own COM+ partition. The default value is **False**.

  Note
  If set to **True**, you must also set a value for the **partitionID** property.

- **Enable or disable session state**

  To enable or disable session state persistence for an ASP application, use the following syntax:

  appcmd set config /section:asp /allowSessionState:True|False

  True enables session state persistence. The default value is **True**.

- **Set maximum number of concurrent sessions**

  To set the maximum number of concurrent sessions that ASP allows, use the following syntax:

  appcmd set config /section:asp /max:*int*

  The variable *int* represents the maximum number of concurrent sessions. The default value is -1.

- **Enable or disable secure session ID**

  To enable or disable the sending of a session ID as a secure cookie if assigned over a secure session channel, use the following syntax:

  appcmd set config /section:asp /keepSessionIdSecure:True|False

  True enables secure session ID. The default value is **True**.

- **Set session time-out**

  To specify the default time that a session object is maintained after the last request associated with the object is made, use the following syntax:

appcmd set config /section:asp /timeout:*timeSpan*

The variable *timeSpan* represents the maximum time (hh:mm:ss) that a session object is maintained after the last request associated with the object is made. The default value is 00:20:00.

Next Steps

Test your website thoroughly to ensure that it functions as expected. Then consider configuring the following features.

- To help you troubleshoot or optimize the performance of your web server, set up IIS logging. For instructions see, Configure Logging in IIS.
- To improve the security of your web server, configure request filtering. For instructions see, Configure Request Filtering in IIS.

Build an ASP.NET Website on IIS

This document contains an overview of the **Build an ASP.NET Website on IIS** scenario. It also contains links to additional information and community resources related to the scenario.

Did you mean…

- Build a Static Website on IIS
- Build a Classic ASP Website on IIS
- Build an FTP Site on IIS
- Build a PHP Website on IIS
- Build an FTP Site on IIS
- Build a Web Farm with IIS Servers

Scenario Description

This scenario shows how to plan and configure an ASP.NET website on an IIS 8 webserver. It is divided into two phases: a plan and design phase, and an install and configure phase. In the plan and design phase, you are provided the information needed to make informed decisions about

web server installation, ASP.NET settings, data source settings, and basic application security. In the install and configure phase, you are guided through the procedures required to install IIS, add an ASP.NET application, and configure IIS.

This scenario does not cover how to write an ASP.NET application.

In This Scenario

- Plan an ASP.NET Website on IIS
  - Step 1: Plan IIS Web Server and ASP.NET Modules Installation
  - Step 2: Plan ASP.NET Settings
  - Step 3: Plan Data Source Settings
  - Step 4: Plan Application Security
- Configure an ASP.NET Website on IIS
  - Step 1: Install IIS and ASP.NET Modules
  - Step 2: Configure ASP.NET Settings
  - Step 3: Configure Data Source Settings
  - Step 4: Configure Application Security

Practical Applications

Whether you are an IT professional, a web developer, or you just want to set up your own webserver, this scenario can help you install IIS and configure it to serve your ASP.NET web application.

Software Requirements

To get the most from this scenario, you must have access to a computer running one of the following operating systems:

- Windows Server® 2012
- Windows® 8

Plan an ASP.NET Website on IIS

To develop a plan for installing an IIS web server and configuring it for ASP.NET web applications, follow the steps listed.

- Step 1: Plan IIS Web Server and ASP.NET Modules Installation
- Step 2: Plan ASP.NET Settings
- Step 3: Plan Data Source Settings
- Step 4: Plan Application Security

After you have reviewed these planning steps, see Configure an ASP.NET Website on IIS. For more information, see Build an ASP.NET Website on IIS.

Step 1: Plan IIS Web Server and ASP.NET Modules Installation

The first step in planning to build an ASP.NET website on IIS 8 is to install IIS along with the ASP.NET modules and to add your application files to IIS.

The following list shows the tasks required to complete this step:

1.1. Plan to Install IIS and ASP.NET Modules

1.2. Plan to Add the ASP.NET Application

When you are done with these tasks, record your design decisions before going on to Step 2: Plan ASP.NET Settings.

1.1. Plan to Install IIS and ASP.NET Modules

An ASP.NET Web server is an extended IIS server that has the ASP.NET runtime extensibility model integrated into the core server. The ASP.NET server configuration adds the following IIS modules to the default IIS web server installation:

- ASP.NET 4.5
- .NET Extensibility 4.5
- ISAPI Extensions
- ISAPI Filters

Important

To install IIS 8 on either Windows Server® 2012 or Windows® 8, you must sign on as a member of the Administrators group.

By default, Windows Server 2012 and Windows 8 installs .NET 4.5 only. If you want to run .NET 2 applications, install .NET 3.5, which supports web applications written using ASP.NET 2 to 3.5.

1.2. Plan to Add the ASP.NET Application

An application is a grouping of content at the root level of a website or a grouping of content in a separate folder under the website root directory. When you add an application in IIS 8, you designate a directory as the *application root*, or starting point, for the application. Then specify properties specific to that particular application, such as the application pool that the application runs in.

To configure your ASP.NET application on an IIS website, provide the following information:

- **Alias**: The alias is used as part of the application root URL and should be short and descriptive. For example, the alias *marketing* added to Default Web Site on the local host computer, would produce the following URL: `//localhost/marketing`.
- **Application pool**: An application pool enables an application or a group of applications to run in isolation from one or more applications in another application pool.
- **Physical path**: The local path to the application files on the server.

- Step 2: Plan ASP.NET Settings
- Plan an ASP.NET Website on IIS
- Build an ASP.NET Website on IIS
- Step 1: Install IIS and ASP.NET Modules

Step 2: Plan ASP.NET Settings

In this phase of building your website, consider the following IIS server and website settings that support ASP.NET:

2.1. Session State Settings

2.2. Pages and Controls Settings

2.3. Application Settings

2.4. .NET Compilation Settings

2.5. .NET Globalization Settings

2.1. Session State Settings

When clients visit a site, they generally navigate from one page to another and frequently change some of the pages they visit. If you want to track pages that users browse and the changes they make during a visit to your website, configure session state.

When session state is enabled for your application, a user receives a unique session ID on their first request to a web page from your ASP.NET application. Session-state data is stored on the server in one of the following ways:

- **In-process**: Session state is stored in the worker process where the ASP.NET application runs.
- **State Server**: Session state is stored outside the worker process where the ASP.NET application runs.
- **SQL Server**: Session state is stored in a SQL Server database.

Note

You can also configure custom out-of-state storage for session-state data. However, it is beyond the scope of this tutorial. Visual Studio 11 project uses custom storage to support SQL Server, SQL Compact, and SQL Azure.

Session-state data can also be stored on the client in a cookie. A cookie is a text file that contains data used for storing information about a user, such as user preferences and user authentication information.

The following sections describe your session-state storage options in more detail.

- Store session state in process
- Store session state by using state server
- Store session state by using SQL server
- Cookie mode for session state

Store session state in process

The in-process session state mode stores session-state data for an ASP.NET application in the worker process where the application runs. This mode is the default for IIS 8.

The advantage of using in-process session state is that it provides the fastest access to session-state data. However, as you store more data in a session, you consume more memory, which can slow server performance.

Before you configure in-process session state, consider the effect of worker process recycling on session state data. If the worker process recycles, all session state data is lost. If your ASP.NET applications must preserve session-state data, and if speed of access to the data is not your primary objective, consider using an out-of-process session state mode for storing this data.

Important
The Windows state service (Aspnet_state.exe) must be running for in-process session state to take effect. By default, this service is installed when Windows Server® 2012 is installed and is configured for manual start. It is recommended that you change the start behavior to Automatic.

By default, the session expires when the user has not requested or refreshed a page in the ASP.NET application for 20 minutes. Because Session objects consume memory on the web server, consider decreasing the time-out value to conserve resources.

Important
Use caution when you adjust the session time-out value, because information stored in a user's Session object is lost when the user is not active on the website for the length of the time-out period.

If you decide to use in-process session-state storage, decide also if you also want to use cookies. For more information about cookies, see Cookie mode for session state.

Store session state by using state server

A *state server* maintains session-state date in memory that is outside the worker process. The advantage of this configuration is that session state is preserved when the application worker process recycles. Using a state server is recommended for medium-sized applications.

A state server depends on the Windows state service (Aspnet_state.exe) and requires a machine key to verify session state across the connection.

When a state server runs on the same web server that contains the applications for which it maintains state, a web garden configuration is supported. For increased protection of session state data, consider using a web farm configuration with a separate server that stores session state and shares it among all servers in the farm. Another approach is to use SQL server to maintain out-of-process session state.

Important
The Windows state service (Aspnet_state.exe) must be running for in-process session state to take effect. By default, this service is installed when Windows Server 2012 is installed and is configured for manual start. Change the start behavior to Automatic.

If you decide to store session state by using a state server, make the following design decisions:

- Define a connection string for the state server.

- Specify the number of seconds to wait before the connection time out.
- Decide whether to enable compression.
- Decide whether to store any session state data in a cookie. For more information about cookies, see Cookie mode for session state.

Store session state by using SQL server

One type of out-of-process session state uses a SQL server to store session state data. The advantage of this configuration is that session state is preserved despite recycling of the application worker process, or if either the Windows state service or the web server goes down.

Note

This setting does not support SQL Azure.

When a SQL server runs on the same web server that has the applications for which it maintains state, it supports a web garden configuration, which increases web server scalability. When the SQL server runs on another server, it supports a web farm configuration, which greatly increases scalability across a group of servers.

Important

The Windows state service (Aspnet_state.exe) must be running for out-of-process session state to take effect. By default, this service is installed when Windows Server 2012 is installed and is configured for manual start. Change the start behavior to Automatic.

Important

Before you configure a SQL server for session state, run the InstallSqlState.sql script on the server. By default, this script is stored in %systemroot%\Microsoft.NET\Framework\V4.0.30319.

If you decide to store session state in a SQL Server database, make the following design decisions:

- Define a connection string for the database.
- Specify the number of seconds to wait before the connection time-out.
- Specify the number of seconds to wait before trying to reconnect.
- Decide whether to enable a custom database.
- Decide whether to enable compression.
- Decide whether to store any session state data in a cookie. For more information about cookies, see Cookie mode for session state.

Cookie mode for session state

One way to track session state for clients that connect to a web server is to use cookies. You can configure a web server to use cookies, not to use cookies, or to select cookie behavior that depends on the browser that is used for the connection.

A session cookie associates session information with client information for the session. A session is the duration of a user's connection to a site. The cookie is passed together with all requests between a client and a web server in an HTTP header.

Using cookies to track session state is more efficient than any other method that does not use cookies, because ookies do not require any redirection. In addition, they allow users to bookmark web pages, and they retain state if a user leaves one site to visit another and then returns to the original site. The one drawback of user cookies is that users can disable cookies in their browser.

The *Use Device Profile* cookie mode causes the brower to use cookies if the it cookies; otherwise, no cookies are used. If the device profile indicates support for cookies, they are used regardless of whether the user has disabled cookie support.

Important

When you use the Use Device Profile cookie mode, set expired session IDs be regenerated. Doing so allows a web server to expire and regenerate tokens, which gives a potential attacker less time to capture a cookie and gain access to web server content.

The *Auto-Detect* cookie mode causes the mobile device to use cookies if its profile supports cookies; otherwise, no cookies are used. For desktop browsers that are known to support cookies, ASP.NET tries to use cookies when cookie support is enabled in the browser. If cookie support is disabled, session state is stored in the URL.

Important

When you use the Auto-Detect cookie mode, set expired session IDs be regenerated. Doing so enables a web server to expire and regenerate tokens, which gives a potential attacker less time to capture a cookie and gain access to web server content. Consider changing the time-out value to less than the 20-minute default.

You can configure session state without using cookies. When you use a Uniform Resource Identifier (URI) to handle session state, the session ID is embedded as a query string in the URI request, and then the URI is redirected to the originally requested URL. The changed URI request is used for the duration of the session, so that no cookie is necessary.

Important

When you use a URI, set expired session IDs be regenerated. Doing so enables a web server to expire and regenerate tokens, which gives a potential attacker less time to capture a cookie and gain access to web server content.

Using a URI to track session state can help you avoid the disadvantages of cookies, including browser support problems and the possibility that users disable cookies. However, using a URI has the following disadvantages:

- Cannot use absolute URLs without losing session state, which means that if a user goes to another application and then returns to the previous one, the user's input no longer exists on the page.
- Does not allow users to bookmark web pages, because session state is lost.

If you decide to use cookies to store session state, make the following design decisions:

- Select a cookie mode: auto detect, use cookies, use device profile, or use URI.

- Unless you selected use URI, specify the name of the cookie.
- Unless you selected use URI, specify the number of minutes before the cookie times out.
- Unless you selected use cookies, decide whether to regenerate an expired session ID.

2.2. Pages and Controls Settings

ASP.NET pages include extra elements that ASP.NET recognizes and processes when the page runs. ASP.NET pages can also contain custom, reusable controls. These custom controls are processed on the server. This lets you use server code to set ASP.NET web page properties.

Note

These settings apply only the ASP.NET Web Forms. They do not apply to ASP.NET MVC or ASP.NET Web Pages.

IIS 8 lets you configure the following ASP.NET page and user controls settings:

- Behavior settings: For example, whether the web page maintains its view state and the view state of any server controls it contains when the current page request ends.
- General settings: For example, namespaces that are included for all pages.
- Compilation settings: For example, whether pages are compiled or interpreted.
- Services: For example, whether session state is enabled.

IIS 8 provides default settings for ASP.NET pages and controls, but you can change those settings as needed. For example, you can set the master page file for a site or enable view state.

Web custom controls are compiled components that run on the server and that encapsulate user-interface and other related functionality into reusable packages. In IIS 8, you can specify the tag prefix and namespace mapping for a custom control that can be used in multiple pages in an application.

Add a custom control when you want to specify the tag prefix/namespace mapping for a custom control that is used in multiple pages in an application.

Note

Adding a configuration setting adds the setting at the local level and to any child levels that inherit the setting.

If you decide to configure ASP.NET custom controls, you need the following information for each control you want to configure:

- I must specify the tag prefix of the control.
- I must specify the .NET namespace of the control.
- I must specify the assembly the control is in.

2.3. Application Settings

Configure application settings when you want to store key/value pairs as part of your configuration in the Web.config file. Application settings provide quick and easy access to stored configuration data for your application.

To manage custom controls, you can view a list that contains all custom controls for a particular configuration level. You can sort this list by tag prefix, source or assembly, or scope (local or inherited). You can also group controls by scope to see which custom controls apply at the current configuration level and which custom controls are inherited from a parent level.

Add a custom control when you want to specify the tag prefix/namespace mapping for a custom control that is used in multiple pages in an application.

Note

Adding a configuration setting adds the setting at the local level and to any child levels that inherit the setting.

If you decide to configure application settings, you need the following information for each setting you want to configure:

1. Specify a name for the setting.
2. Specify a value for the setting.

2.4. .NET Compilation Settings

For application code to service requests by users, ASP.NET must first compile the code into one or more assemblies. Assemblies are files that have the file name extension .dll. Configure .NET compilation settings in IIS 8 when you want to control how ASP.NET code is compiled.

IIS lets you configure the following .NET compilation settings:

- Batch settings, such as the maximum file size that you can batch and the maximum number of pages that you can have per batched compilation.
- Behavior settings, such as the number of times resources are dynamically compiled before the application is restarted.
- General settings, such as the default programming language that is used in dynamic compilation files.

2.5. .NET Globalization Settings

Globalization is the process of internationalizing application code, then localizing the application to other languages and cultures. The internationalization process makes it possible to translate, store, retrieve, and present application content for any locale by using the same application code base whenever possible. Locale is the combination of both language and cultural environment. This includes date formats, times, currencies, telephone numbers, and so on. Localization means adapting your application to other locales by translating and formatting content according to culture, preferably without touching the code.

You can change globalization settings for ASP.NET applications at the web server level when you want them to apply to all ASP.NET applications on the server. You can also edit ASP.NET globalization settings for sites, applications, directories, and files.

IIS lets you configure the following globalization settings:

- Culture settings, such as the UI culture or UI language.

- Encoding settings, such as encoding for response headers.

Note
Editing a configuration setting changes the setting at the local level and for any child levels that inherit the setting.

Step 3: Plan Data Source Settings

In this phase of building your website, consider the data storage needs of your ASP.NET application. The following sections describe various data-source settings available in IIS:

3.1. Data source connection strings

3.2. ASP.NET providers

3.3. .NET profiles

3.4. .NET roles

3.5. .NET users

3.1. Data source connection strings

A connection string provides the information that an application or provider must have to communicate with a particular database. A connection string usually supplies the server or location of the database server, the particular database to use, and the authentication information. A connection string enables you to connect to databases from managed code applications in a centralized manner.

Adding a configuration setting adds the setting at the local level and to any child levels that inherit the setting.

To add a connection string to IIS, provide the following information:

- Specify a name for the connection string. This name must be the same name you reference in your application code to retrieve data from the database.
- Specify the server the database is on.
- Specify the name of the database.
- Provide the credentials, unless using Windows integrate security.

3.2. ASP.NET providers

ASP.NET 2.0 includes several services that store state in a database or other data store. A provider is a software module that implements a uniform interface between one of these services and a data source. In IIS 7, you can set the default provider for your application. You can also configure the provider properties. For example, **Users** is a provider-based feature where one provider stores the user data in SQL whereas another provider stores the user data in a text file.

Add a provider in IIS when you have an application that uses a provider-based service to store data in a database or other data store. For example, the session state service in ASP.NET is a provider-based service that manages per-user session state by storing it in process (in memory in the application domain of the host application), in memory in an external process (the "state server process"), or in a Microsoft SQL Server database.

Adding a configuration setting adds the setting at the local level and to any child levels that inherit the setting.

To add a provider for your application, provide the following configuration information:

- Select the IIS feature for the provider to provide: .NET Profiles, .NET Roles, or .NET Users.
- Select the provider type.
- Enter a name for the provider.
- If the feature selected is .NET Users, select any of the following provider behaviors that you want:
  - Enable password reset
  - Enable password retrieval
  - Requires question and answer
  - Requires unique email
  - Store password in secure format
- Provide the name of the connection string to the database.
- Enter the name of the application.

3.3. .NET profiles

The .NET profile feature associates information with an individual user and stores the information in a persistent format. .NET profiles let you manage user information without requiring you to create and maintain your own database.

In .NET profile, you can add properties or groups. A property stores information that is unique to a user, such as the user name. You can then use the information you have stored to present the user with a personalized version of your application. A group organizes related properties together. For example, the different properties of a user’s address information can be grouped together in an Address group.

If you decide to add profile properties or groups for your ASP.NET application, provide the following information:

- For each profile property, provide the property name, data type (such as string or Boolean), a default value, a serialization option (string, XML, binary, or provider specific), whether it is read-only, and whether it is available for anonymous users.
- For each profile group, provide the group name.

3.4. .NET roles

Roles give you an easy way to manage access rules for groups of users. You create users and then assign the users to roles (in Windows, you assign users to groups). For example, you can create a set of pages that you want to restrict to certain users and store those pages in a folder by themselves. Then you can use IIS 8 to define rules that grant and deny access to restricted folders. If an unauthorized user tries to view a restricted page, the user either sees an error or is redirected to a page that you specify.

Roles do not work with anonymous users who access a site, application, or file.

Add roles when you have security settings that you want to apply to a group of users who differ from all existing groups.

If you decide to define roles for your application, provide a name for each role.

Important

To configure roles for your application, you must have previously configured a .NET roles provider.

3.5. .NET users

Associating user identities with an application helps you manage authentication, authorization, and other security-related operations for that application.

Add a user when you want to use IIS to define a user name, e-mail address, password, and security question for initiating an automatic account reset if a user loses or forgets their password. If the **.NET Roles** feature is enabled, you can add users to roles as you create them.

If you decide to configure users for your application, provide the following information for each user:

- User Name (must be unique).
- E-mail (must use standard format: name@domain.com).
- Password (must be a strong password).
- Question (enter a custom question or select from the list).
- Answer to the foregoing question.
- Roles the user is assigned to.

Important

To configure users for your application, you must have previously configured a .NET users provider.

Step 4: Plan Application Security

In this phase of building your website, consider the security needs of your ASP.NET application. The following sections describe application security settings available in IIS 8:

4.1. Isolate Web Applications
4.2. .NET Trust Levels
4.3. .NET Authentication
4.4. Machine Key Settings
4.5. TLS/SSL Communication

4.1. Isolate Web Applications

One of the most effective ways to improve security for your web application is to isolate it from other applications on your web server. An application pool has its own worker process, which processes requests and runs application code. The worker process has a security identifier (SID). And each application pool has a unique application-pool identity. By default, when you create a web application, a new application pool is also created with the same name as the application. If you keep web applications in separate application pools, you can isolate them from one another.

Web application isolation entails the following:

- Site isolation: Separate different applications into different sites with different application pools.
- Least privilege: Run your worker process as a low privileged identity (virtual application pool identity) that is unique per site.
- Temp isolation: Set up a separate ASP.NET temp folder per site and only give access to appropriate process identity.
- Content isolation: Make sure to set an ACL (access control list) on each site root to allow only access to the appropriate process identity.

Tip

It is a good idea to host your website and web application content on a drive other than your system drive (C:).

4.2. .NET Trust Levels

An application *trust level* determines the permissions that the ASP.NET code access security (CAS) policy grants. CAS defines two trust categories: full trust and partial trust. An application that has full trust permissions can access all resource types on a server and perform privileged operations. Applications with full trust are affected only by the security settings of the operating system.

Partial-trust web applications are applications that do not have full trust and have a restricted set of code access permissions. As a result, partial-trust applications are limited in their ability to access secured resources and perform other privileged operations. Certain permissions are denied to partial-trust applications, so resources that require those permissions cannot be directly accessed. Other permissions are granted in a restricted way, so resources that require those permissions might be accessible, but in a limited way. For example, restricted file IO permission

give the application can access to the file system, but only in directories beneath the application's virtual directory root.

By configuring a web application or web service for partial trust, you can restrict the application ability to access crucial system resources or resources that belong to other web applications. By granting only the permissions that the application requires and no more, you can build least privileged web applications and limit potential damage if the web application is compromised by a code injection attack.

The following list shows the restrictions associated with each trust level:

- Full trust applications have unrestricted access to all resource types and can perform privileged operations.
- High, medium, low, or minimal trust applications are unable to call unmanaged code or serviced components, write to the event log, access Message Queuing queues, or access OLE DB data sources.
- High trust applications have unrestricted access to the file system.
- Medium trust applications have restricted file system access and can only access files in their own application-directory hierarchy.
- Low or minimal trust applications cannot access SQL Server databases.
- Minimal trust applications cannot access any resources.

4.3. .NET Authentication

Authentication helps you confirm the identity of clients who request access to your sites and applications. When authentication is enabled, IIS 8 uses the account credentials supplied by the user to determine what permissions the user has been granted and what resources the user can access.

This section describes the authentication modes that are specific to ASP.NET applications.

1. ASP.NET Forms Authentication
2. ASP.NET Impersonation Authentication

ASP.NET Forms Authentication

Forms authentication uses client-side redirection to forward unauthenticated users to an HTML form where they can enter their credentials, which are usually a user name and password. After the credentials are validated, users are redirected to the page they originally requested. Forms authentication often employs cookies to pass user credentials between the server and the client browser.

The following sections describe what you need to know to plan adding forms authentication to your site:

1. Forms authentication basics
2. Authentication cookies

Forms authentication basics

ASP.NET Forms-based authentication works well for sites or applications on public web servers that receive many requests. This authentication mode lets you manage client registration and authentication at the application level, instead of relying on the authentication mechanisms the operating system provides.

Important
Because Forms authentication sends the user name and password to the web server as plaintext, use Secure Sockets Layer (SSL) encryption for the logon page and for all other pages in your application except the home page. For information about SSL, see 4.5. TLS/SSL Communication.

Forms authentication lets users log on by using identities from an ASP.NET membership database. This authentication method uses redirection to an HTML logon page to confirm the identity of the user. You can configure Forms authentication at the site or application levels.

Forms authentication is convenient for the following reasons:

- It allows either a custom data store, such as a SQL server database, or Active Directory to be used for authentication.
- It integrates easily with a web user interface.
- Clients can use any browser.

If you want to use membership roles for authorization, use Forms authentication or a similar custom authentication method.

Important
If you select Forms authentication, you cannot use any of the challenge-based authentication methods at the same time.

By default, the login URL for Forms authentication is Login.aspx. You can create a unique login page for clients who visit a site or application. For example, you might want to collect specific information from visitors, or offer membership to selected pages on the site or selected applications.

The default time-out value for Forms authentication is 30 minutes. Consider changing the time-out value to a shorter period, to shorten the session lifetime and to reduce the chance of cookie replay attacks.

Authentication cookies

Authentication cookies are used as a token to verify that a client has access to some or all pages of an application. By contrast, personalization cookies contain user-specific settings that determine user experience on a specific site or application.

Important
Because authentication cookies are passed between client and server together with every request, always secure authentication cookies using Secure Sockets Layer (SSL). For information about SSL, see 4.5. TLS/SSL Communication.

Cookies are a more efficient way to track visitors to a site than query strings, because they do not require redirection. However, they are browser-dependent, and some browsers do not support their use. In addition, the use of cookie-based authentication is not always effective because some users disable cookie support in their browsers.

By default, the cookie name for ASP.NET applications is .ASPXAUTH. However, you can instead use a unique cookie name and path for each application. Doing so can prevent users who are authenticated for one application from being authenticated for other applications on a web server.

You can choose one of the following cookie modes for your site or application.

Mode	Description
Use cookies	Cookies are always used regardless of device.
Do not use cookies	Cookies are not used.
Auto Detect	Cookies are used if the device profile supports cookies. Otherwise, no cookies are used. For desktop browsers that are known to support cookies, ASP.NET checks to determine whether cookies are enabled. This setting is the default.
Use device profile	Cookies are used if the device profile supports cookies. Otherwise, no cookies are used. ASP.NET does not check to determine whether cookies are enabled on devices that support cookies. This setting is the default for IIS 8.

The cookie protection mode defines the function a Forms authentication cookie performs for a specific application. The following table shows the cookie protection modes that you can define:

Mode	Description
Encryption and validation	Specifies that the application use both data validation and encryption to help protect the cookie. This option uses the configured data validation algorithm (based on the machine key). If triple-DES (3DES) is available and if the key is long enough (48 bytes or more 3DES is used for encryption. This setting is the default (and recommended) value.
None	Specifies that both encryption and validation are disabled for sites that are using cookies only for personalization and have weaker

Mode	Description
	security requirements. We do not recommend that you use cookies in this manner; however, it is the least resource-intensive way to enable personalization by using the .NET Framework.
Encryption	Specifies that the cookie is encrypted by using Triple-DES or DES, but data validation is not performed on the cookie. Cookies used in this manner might be subject to plaintext attacks.
Validation	Specifies that a validation scheme verifies that the contents of an encrypted cookie have not been changed in transit.

Important
For security reasons, consider keeping Encryption and Validation cookies separate from each other. The theft of encryption cookies would be a greater security exposure than the theft of validation cookies.

If an application contains objects that clients request frequently, improve application performance by caching those objects. If the user accesses the cached object before the authentication cookie times out, IIS 8 allows the cached object to remain in the cache, and the timer is reset. However, if the user does not access the cached object during that time, IIS 8 removes the cached object from the cache.

Consider enabling this setting under the following circumstances:

- You have a limited amount of memory available for caching.
- You have many objects to cache, because this setting allows only the most frequently requested objects to remain in the cache.

Note
You specify the number of minutes before an authentication cookie times out with **Authentication cookie time-out (in minutes)**.

ASP.NET Impersonation Authentication

Use ASP.NET impersonation when you want to run your ASP.NET application under a security context different from the default security context for ASP.NET applications.

If you enable impersonation for an ASP.NET application, that application can run in one of two different contexts: either as the user authenticated by IIS 8 or as an arbitrary account that you set up. For example, if you use Anonymous authentication and choose to run the ASP.NET application as the authenticated user, the application would run under an account that is set up for anonymous users (typically, IUSR). Likewise, if you chose to run the application under an arbitrary account, it would run under whatever security context was set up for that account.

By default, ASP.NET impersonation is disabled. If you enable impersonation, your ASP.NET application runs under the security context of the user authenticated by IIS 8.

4.4. Machine Key Settings

Machine keys help protect Forms authentication cookie data and page-level view state data. They also verify out-of-process session state identification. ASP.NET uses the following types of machine keys:

- A *validation key* computes a Message Authentication Code (MAC) to confirm the integrity of the data. This key is appended to either the Forms authentication cookie or the view state for a specific page.
- A *decryption key* is used to encrypt and decrypt Forms authentication tickets and view state.

IIS 8 enables you to configure validation and encryption settings and generate machine keys for use with ASP.NET application services, such as view state, forms authentication, membership, roles, and anonymous identification.

Before you generate machine keys for your application, make the following design decisions:

- Decide what validation method to use: AES, MD5, SHA1 (default), TripleDES, HMACSHA256, HMACSHA384, or HMACSHA512.
- Decide what encryption method to use: Auto (default), AES, TripleDES, or DES.
- Decide whether to generate the validation key at runtime automatically.
- Decide whether to generate a unique validation key for each application.
- Decide whether to generate the decryption key at runtime automatically.
- Decide whether to generate a unique decryption key for each application.

4.5. TLS/SSL Communication

Transport Layer Security (TLS) and its predecessor, Secure Sockets Layer (SSL) are protocols that provide communication security your website. You can use TLS/SSL to authenticate servers and clients and then use it to encrypt messages between the authenticated parties.

In the authentication process, a TLS/SSL client sends a message to a TLS/SSL server, and the server responds with the information that the server needs to authenticate itself. The client and server perform an additional exchange of session keys, and the authentication dialog ends. When authentication is completed, SSL-secured communication can begin between the server and the client by using the symmetric encryption keys that are established during the authentication process.

To configure TSL/SSL for your website, do the following:

1. Obtain a server certificate from a certification authority (CA). See Server Certificates.
2. Add SSL binding to the site. See SSL Binding.
3. Set IIS to require SSL on the site. See Require SSL for Your Site.
4. Consider using client certificates for your site. See Client Certificates.

Server Certificates

You can obtain a server certificate from a certification authority (CA). Obtaining a server certificate from a certification authority is one step in configuring Secure Sockets Layer (SSL) or Transport Layer Security (TLS). You can obtain server certificates from a third-party CA. A third-party CA might require you to provide proof of identity before a certificate is issued. You can also issue your own server certificates by using an online CA, such as Microsoft Certificate Services.

Digital certificates are electronic files that work like an online password to verify the identity of a user or a computer. They are used to create the SSL encrypted channel that is used for client communications. A certificate is a digital statement that is issued by a certification authority (CA) that vouches for the identity of the certificate holder and enables the parties to communicate in a secure manner by using encryption.

Digital certificates do the following:

- They authenticate that their holders—people, web sites, and even network resources such as routers—are truly who or what they claim to be.
- They protect data that is exchanged online from theft or tampering.

Digital certificates are issued by a trusted third-party CA or a Microsoft Windows public key infrastructure (PKI) using Certificate Services, or they can be self-signed. Each type of certificate has advantages and disadvantages. Each type of digital certificate is tamper-proof and can't be forged.

Certificates can be issued for several uses. These uses include web user authentication, web server authentication, Secure/Multipurpose Internet Mail Extensions (S/MIME), Internet Protocol security (IPsec), Transport Layer Security (TLS), and code signing.

A certificate contains a public key and attaches that public key to the identity of a person, computer, or service that holds the corresponding private key. The public and private keys are used by the client and the server to encrypt the data before it is transmitted. For Windows-based users, computers, and services, trust in a CA is established when there is a copy of the root certificate in the trusted root certificate store and the certificate contains a valid certification path. For the certificate to be valid, the certificate must not have been revoked and the validity period must not have expired.

SSL Binding

You can assign multiple bindings to a site when you have site content that serves different purposes or for which you must use a different protocol. For example, a commerce site might have an application that requires that users log on to an account to purchase merchandise. The company hosts the site over HTTP, but users must log on to their account on an HTTPS page. In this example, the site would have two bindings: one for the HTTP portion and one for the HTTPS portion.

Out of the box, you cannot add bindings for protocols other than HTTP and HTTPS by using IIS Manager. If you want to add a binding for a different protocol, such as a protocol supported by Windows Communication Foundation (WCF), use one of the other administration tools. However, if you install the IIS File Transfer Protocol (FTP) server, you can add FTP bindings by using IIS

Manager. There might also be other modules or third-party functionality available for download that extend the UI.

Require SSL for Your Site

Secure Sockets Layer (SSL) encryption protects confidential or personal information sent between a client and a server. When SSL is enabled, remote clients access your site by using URLs that start with https://.

First configure a server certificate and create an HTTPS binding to enable any SSL settings. Then require Secure Sockets Layer (SSL) encryption in one or more of the following circumstances:

1. When confidential or personal content on your server must be protected by an encrypted channel.
2. When you want users to be able to confirm the identity of your server before they transmit personal information.
3. When you want to use client certificates to authenticate clients that access your server.

Client Certificates

When you want clients to verify their identity before they access content on your web server, configure client certificates. By default, client certificates are ignored.

Before you can configure client certificate on your website, configure a server certificate and create an HTTPS binding to enable any Secure Sockets Layer (SSL) settings.

If you want all clients to verify their identity, specify that client certificates are required. If some clients can access content without first verifying their identity, specify that client certificates are accepted.

Configure an ASP.NET Website on IIS

To install an IIS web server and configure it for ASP.NET web applications, follow the steps listed.

- Step 1: Install IIS and ASP.NET Modules
- Step 2: Configure ASP.NET Settings
- Step 3: Configure Data Source Settings
- Step 4: Configure Application Security

For planning information to review before deployment, see Plan an ASP.NET Website on IIS. For more information, see Build an ASP.NET Website on IIS.

Step 1: Install IIS and ASP.NET Modules

The first step in building an ASP.NET website on IIS 8 is to install IIS along with the ASP.NET modules. Then add your ASP.NET application files to IIS.

The following list shows the tasks required to complete this step:

Installing IIS and ASP.NET Modules

Adding the ASP.NET Application

When you are done, make sure that IIS and the ASP.NET modules are installed, and your ASP.NET application has been added to your website. Then go on to Step 2: Configure ASP.NET Settings.

Installing IIS and ASP.NET Modules

This section describes how to install IIS and the modules that support ASP.NET applications in any of the following ways:

- Install IIS on Windows Server® 2012 using the IIS Manager UI.
- Install IIS on Windows® 8 using the IIS Manager UI.
- Install IIS using the command line.

Important
To install IIS on either Windows Server 2012 or Windows 8, you must sign on as a member of the Administrators group.

If you prefer, you could use the Web Platform Installer (Web PI) to install IIS and third-party applications that run on IIS. Because the Web PI installs the latest versions of available Web Platform offerings, with just a few simple clicks you can download and install any new tools or updates. To learn more about the Web PI, see Learn more and install the Web PI.

If you support web applications written using ASP.NET 2 to 3.5, install .NET 3.5 before installing IIS and ASP.NET modules.

To install .NET 3.5 on Windows Server 2012 or Windows 8

1. On the **Start** screen, right-click the **Command Prompt** tile, and then click **Run as administrator**.
2. At the command prompt, type the following: **dism /online /enable-feature /featurename:netfx3**
3. Wait for the command to complete. It could take several minutes.
4. Close the command prompt window.

To install IIS and ASP.NET modules on Windows Server 2012 using the UI

1. On the **Start** page, click the **Server Manager** tile, and then click **OK**.
2. In **Server Manager**, select **Dashboard**, and click **Add roles and features**.
3. In the **Add Roles and Features Wizard**, on the **Before you begin** page, click **Next**.
4. On the **Select installation type** page, select Role-based or feature-based installation, and click **Next**.
5. On the **Select destination server** page, select **Select a server from the server pool**, select your server, and click **Next**.
6. On the **Select server roles** page, select **Web Server (IIS)**, and click **Next**.
7. On the **Select features** page, click **Next**.
8. On the **Web Server Role (IIS)** page, click **Next**.
9. On the **Select role services** page, note the preselected role services that are installed by default, expand the **Application Development** node, and then select **ASP.NET 4.5**. (If you installed **.NET 3.5**, select **ASP.NET 3.5** also.)
10. On the **Summary of Features to Install** page, confirm your selections, and then click **Install**.
11. In the **Add features that are required for ASP.NET 4.5?** box, click **Add Features**.

    The following additional features are added:

    - **.NET Extensibility 4.5**
    - **ISAPI Extensions**
    - **ISAPI Filters**
    - **.NET Extensibility 3.5** (If **ASP.NET 3.5** was selected)
12. Click **Next**.
13. On the **Confirm installation selections** page, click **Install**.
14. On the **Installation progress** page, confirm that your installation of the Web Server (IIS) role and required role services completed successfully, and then click **Close**.
15. To verify that IIS installed successfully, type the following into a web browser:

    http://localhost

    The default IIS Welcome page is displayed.

To install IIS and ASP.NET modules on Windows 8 by using the UI

1. On the **Start** page, click the **Control Panel** tile.
2. In **Control Panel**, click **Programs**, and then click **Turn Windows features on or off**.
3. In the **Windows Features** dialog box, click **Internet Information Services** to install the default features.
4. Expand the **Application Development Features** node and click **ASP.NET 4.5** to add the features that support ASP.NET. (If you installed **.NET 3.5**, select **ASP.NET 3.5** also.)

   The following additional features are automatically selected:

- **.NET Extensibility 4.5**
- **ISAPI Extensions**
- **ISAPI Filters**
- **.NET Extensibility 3.5** (If **ASP.NET 3.5** was selected)

5. Click **OK** to close the **Windows Features** dialog box.
6. To verify that IIS installed successfully, type the following into a web browser:

   http://localhost

   The default IIS Welcome page is displayed.

To install IIS and ASP.NET modules by using the command line

- Type the following command at a Command Prompt or into a script:

  Start /w pkgmgr /iu:IIS-WebServerRole;IIS-WebServer;IIS-CommonHttpFeatures;IIS-StaticContent;IIS-DefaultDocument;IIS-DirectoryBrowsing;IIS-HttpErrors;IIS-ApplicationDevelopment;IIS-ASPNET;IIS-NetFxExtensibility;IIS-ISAPIExtensions;IIS-ISAPIFilter;IIS-HealthAndDiagnostics;IIS-HttpLogging;IIS-LoggingLibraries;IIS-RequestMonitor;IIS-Security;IIS-RequestFiltering;IIS-HttpCompressionStatic;IIS-WebServerManagementTools;IIS-ManagementConsole;WAS-WindowsActivationService;WAS-ProcessModel;WAS-NetFxEnvironment;WAS-ConfigurationAPI

Adding the ASP.NET Application

This section describes how to add your ASP.NET application to your website in the following ways:

- Adding an ASP.NET Application with the IIS Manager UI
- Adding an ASP.NET application with the command line

In Plan an ASP.NET Website on IIS, you made the following decisions:

- Alias string that becomes part of the application root URL.
- Application pool to run the application in.
- Physical path to the application files on the server.

To add an ASP.NET application by using the UI

1. Open IIS Manager.
   - For Windows Server 2012, on the **Start** page click the **Server Manager** tile, and then click **OK**. In **Server Manager**, click the **Tools** menu, and then click **Internet Information Services (IIS) Manager**.
   - For Windows 8, on the **Start** page type **Control Panel**, and then click the **Control Panel** icon in the search results. On the **Control Panel** screen, click **System and Security**, click **Administrative Tools**, and then **click Internet Information Services**

(IIS) Manager.

2. In the **Connections** pane, expand the **Sites** node.
3. Right-click the site for which you want to create an application, and click **Add Application**.
4. In the **Alias** text box, type a value for the application URL, such as **marketing**. This value is used to access the application in a URL.
5. Click **Select** if you want to select a different application pool than the one listed in the **Application pool** box. In the **Select Application Pool** dialog box, select an application pool from the **Application pool** list and then click **OK**.
6. In the **Physical path** text box, type the physical path of the application's folder, or click the browse button (**...**) to navigate the file system to find the folder.
7. Optionally, click **Connect as** to specify credentials that have permission to access the physical path. If you do not use specific credentials, select the **Application user (pass-through authentication)** option on the **Connect As** dialog box.
8. Optionally, click **Test Settings** to verify the settings that you specified for the application.
9. Click **OK**.

To add an ASP.NET application by using the command line

- To add an application to a site, use the following syntax:

  appcmd add app /site.name:*string* **/path:***string* **/physicalPath:***string*

  The variable **site.name** *string* is the name of the website to which you want to add the application. The variable **path** *string* is the virtual path of the application, such as **/application**, and **physicalPath** *string* is the physical path of the application content in the file system.

  For example, to add an application named **marketing** to a site named **contoso**, with content at **c:\application**, type the following at the command prompt, and then press ENTER:

  appcmd add app /site.name:contoso /path:/marketing /physicalPath:c:\application

See Also

- Step 2: Configure ASP.NET Settings
- Configure an ASP.NET Website on IIS
- Build an ASP.NET Website on IIS
- Step 1: Plan IIS Web Server and ASP.NET Modules Installation

Step 2: Configure ASP.NET Settings

In this phase of building your website, you configure the following IIS server and website settings that support ASP.NET:

2.1. Session State Settings
2.2. Pages and Controls Settings
2.3. Application Settings
2.4. .NET Compilation Settings
2.5. .NET Globalization Settings

2.1. Session State Settings

In Plan an ASP.NET Website on IIS, you decided to use one of the following session-state-storage options:

- **In-process**: Session state is stored in the worker process where the ASP.NET application runs.
- **State Server**: Session state is stored outside the worker process where the ASP.NET application runs.
- **SQL Server**: Session state is stored in a SQL Server database.

You might have also chosen to store session data on the client computer in a cookie. You can even combine the use of cookies with one of the other storage methods. For example, you could store authentication data in a cookie while storing other session-state data in a SQL Server database.

The following sections describe how to configure session state based on the planning decisions you have made:

- Store Session State in Process
- Store Session State by using State Server
- Store Session State by using SQL Server
- Cookie Mode for Session State

Store Session State in Process

This section describes how to configure in-process session state by using either the IIS Manager UI or the command line.

To enable in-process session state by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Session State**.
3. On the **Session State** page, in the **Session State Mode Settings** area, click **In process**.
4. (Optional) Configure cookie settings in the **Cookie Settings** area on the **Session State** page.

   For more information about cookie settings, see Cookie Mode for Session State.
5. In the **Time-out** field, enter a time-out value in the format hh:mm:ss. For example, enter

00:15:00 for 15 minutes.

6. (Optional) Check the **Use hosting identity for impersonation** check box to use Windows authentication and the host process identity (either ASP.NET or a Windows service identity) for remote connections.
7. Click **Apply** in the **Actions** pane.

To enable in-process session state by using the command line

- To enable in-process session state, use the following syntax:

  appcmd set config /commit:WEBROOT /section:sessionState /mode:InProc

  The variable **mode:InProc** enables in-process session state. By default, in-process session state is enabled.

  Note
  When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To specify the default time that a session object is maintained after the last request associated with the object is made, use the following syntax:

  appcmd set config /section:asp /timeout:*timeSpan*

  The variable *timeSpan* represents the maximum time (hh:mm:ss) that a session object is maintained after the last request associated with the object is made. The default value is 00:20:00.

Store Session State by using State Server

This section describes how to configure a state server for session-state storage by using either the IIS Manager UI or the command line.

In Plan an ASP.NET Website on IIS, you made the following design decisions:

- Define a connection string for the state server.
- Specify the number of seconds to wait before the connection time-out.
- Decide whether to enable compression.
- Decide whether to store any session state data in a cookie.

To configure a state server to maintain session state by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Session State**.
3. On the **Session State** page, in the **Session State Mode Settings** area, click **State Server.**
4. Type a connection string in the **Connection string** text box, or click **Create** to create a connection string.

5. Type a time-out value in the **Time-out (in seconds)** text box. The default time-out value is 10 seconds.
6. (Optional) Configure cookie settings in the **Cookie Settings** area on the **Session State** page.

   For more information about cookie settings, see Cookie Mode for Session State.
7. (Optional) Select the **Use hosting identity for impersonation** check box to use Windows authentication and the host process identity (either ASP.NET or a Windows service identity) for connections to the database.
8. Click **Apply** in the **Actions** pane.

To configure a state server to maintain session state by using the command line

- To configure a state server to maintain session state, use the following syntax:

  appcmd set config /commit:WEBROOT /section:sessionState /mode:StateServer /stateConnectionString:*string* **/stateNetworkTimeout:** *timeSpan* **/useHostingIdentity:True|False**

  The variable **mode:StateServer** sets the session state mode to store session data in a state server. By default, the variable *string* defines the connection string that the state server uses. The default setting is tcpip=loopback:42424. The variable *timeSpan* sets the time, in seconds, that the connection to the state server is maintained. The default is 10 seconds. The variable **useHostingIdentity:True|False** enables or disables the use of Windows authentication and the host process identity (either ASP.NET or a Windows service identity) for connections to the database. The default value is **True**.

  Note
  When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

Store Session State by using SQL Server

This section describes how to configure a SQL Server database for session-state storage using either the IIS Manager UI or the command line.

In Plan an ASP.NET Website on IIS, you made the following design decisions:

- Define a connection string for the database.
- Specify the number of seconds to wait before the connection time-out.
- Specify the number of seconds to wait before trying to reconnect.
- Decide whether to enable a custom database.
- Decide whether to enable compression.
- Decide whether to store any session state data in a cookie.

To configure a SQL server to maintain session state by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Session State**.
3. On the **Session State** page, in the **Session State Mode Settings** area, click **SQL Server**.
4. Type a connection string in the **Connection string** text box, or click **Create** to create a connection string. If the SQL server is on the server you are managing, select **LocalSqlServer** in the **Connection string** text box.
5. Type a time-out value in the **Time-out** text box.
6. (Optional) Check the **Enable custom database** check box to use a custom database for storing session state data.
7. (Optional) Configure cookie settings in the **Cookie Settings** area on the **Session State** page.

   For more information about cookie settings, see Cookie Mode for Session State.
8. (Optional) Check the **Use hosting identity for impersonation** check box to use Windows authentication and the host process identity (either ASP.NET or a Windows service identity) for remote connections to the SQL database.
9. Click **Apply** in the **Actions** pane.

To configure a SQL server to maintain session state by using the command line

1. To configure a state server to maintain session state, use the following syntax:

   appcmd set config /commit:WEBROOT /section:sessionState /mode:SqlServer /sqlConnectionString:*string* **/sqlCommandTimeout:** *timeSpan* **/useHostingIdentity:True|False**

   The variable **mode:SqlServer** sets the session state mode to store session data in a SQL server database. By default, the variable *string* defines the connection string that the SQL server uses. The default setting is LocalSqlServer. The variable *timeSpan* sets the time, in seconds, that the connection to the SQL server is maintained. The default is 30 seconds. The variable **useHostingIdentity:True|False** enables or disables the use of Windows authentication and the host process identity (either ASP.NET or a Windows service identity) for connections to the database. The default value is **True**.

   Note

   When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

Cookie Mode for Session State

This section describes how to configure a SQL Server database for session-state storage by using either the IIS Manager UI or the command line.

In Plan an ASP.NET Website on IIS, you made the following design decisions:

- Select a cookie mode: auto detect, use cookies, use device profile, or use URI.
- Unless you selected use URI, specify the name of the cookie.
- Unless you selected use URI, specify the number of minutes before the cookie times out.
- Unless you selected use cookies, decide whether to regenerate an expired session ID.

To configure Use Cookies mode for session state by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Session State**.
3. On the **Session State** page, in the **Cookie Settings** area, select **Use Cookies** from the **Mode** drop-down list.
4. Type a cookie name in the **Name** text box, or use the default cookie name, ASP.NET_SessionId.
5. Type a time-out value in the **Time-out** text box, or use 20 minutes, the default time-out value.
6. Click **Apply** in the **Actions** pane.

To configure Use Cookies mode for session state by using the command line

- To configure use cookies mode for session state, use the following syntax:

  appcmd set config /commit:WEBROOT /section:sessionState /cookieless:UseCookies /cookieName:string **/timeout:**timeSpan

  The variable **cookieless:UseCookies** configures IIS 8 to use cookies mode for session state. This is the default value. The variable *string* is the name of the cookie. The default value is **ASP.NET_SessionId**. The variable *timeSpan* sets the time, in minutes, after which the cookie times out. The default is 20 minutes. For example, to set a cookie-mode cookie for session state (called MyCookie and that expires after 40 minutes), type the following at the command prompt, and then press Enter:

  appcmd set config /commit:WEBROOT /section:sessionState /cookieless:UseCookies /cookieName:MyCookie /timeout:40

  Note

  When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To configure use device profile cookie mode for session state, use the following syntax:

  appcmd set config /commit:WEBROOT /section:sessionState

/cookieless:UseDeviceProfile /cookieName:string **/timeout:**timeSpan **/regenerateExpiredSessionId:True|False**

The variable **cookieless:UseDeviceProfile** configures IIS 8 to use device-profile cookie mode for session state. The variable *string* is the name of the cookie. The default value is **ASP.NET_SessionId**. The variable *timeSpan* sets the time, in minutes, after which the cookie times out. The default is 20 minutes. The variable **regenerateExpiredSessionId:True|False** enables or disables the regeneration of expired session IDs.

Note

When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To configure auto-detect cookie mode for session state, use the following syntax:

  appcmd set config /commit:WEBROOT /section:sessionState /cookieless:AutoDetect /cookieName:string **/timeout:**timeSpan **/regenerateExpiredSessionId:True|False**

  The variable **cookieless:AutoDetect** configures IIS 8 to use auto-detect cookie mode for session state. The variable *string* is the name of the cookie. The default value is **ASP.NET_SessionId**. The variable *timeSpan* sets the time, in minutes, after which the cookie times out. The default is 20 minutes. The variable **regenerateExpiredSessionId:True|False** enables or disables the regeneration of expired session IDs.

  Note

  When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To configure URI cookie mode for session state, use the following syntax:

  appcmd set config /commit:WEBROOT /section:sessionState /cookieless:UseUri /regenerateExpiredSessionId:True|False

  The variable **cookieless:UseUri** configures IIS 8 to use URI cookie mode for session state. The variable **regenerateExpiredSessionId:True|False** enables or disables the regeneration of expired session IDs.

  Note

  When you use Appcmd.exe to configure the **<sessionState>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

2.2. Pages and Controls Settings

This section describes how to configure ASP.NET pages and control settings by using either the IIS Manager UI or the command line.

Note
These settings apply only to ASP.NET Web Forms. They do not apply to ASP.NET MVC or ASP.NET Web Pages.

Edit Pages and Controls

You can edit the settings of existing pages and controls, and the changes are reflected into the Web.config file.

To edit settings for pages and controls by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Pages and Controls**.
3. On the **Pages and Controls** page, edit settings as necessary.
4. When finished, click **Apply** in the **Actions** pane.

To edit settings for pages and controls by using the command line

- To enable or disable page output buffering, use the following syntax:
  appcmd set config /commit:WEBROOT /section:pages /buffer:True|False
  The variable **buffer:True** enables buffering of page output. The default is **True**.

Add a Custom Control

In Plan an ASP.NET Website on IIS, you made the following design decisions for each custom control you want to add:

- Specify the tag prefix of the control.
- Specify the .NET namespace of the control.
- Specify the assembly the control is in.

To add a custom control by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Pages and Controls**.
3. In the **Actions** pane, click **Register Controls**.
4. In the **Actions** pane, click **Add Custom Control**.
5. In the **Add Custom Control** dialog box, type a tag prefix in the **Tag prefix** text box.
6. In the **Namespace** text box, type the namespace to which the custom control belongs. This is the same namespace that was specified in the application code.

7. In the **Assembly** text box, type the name of the source or assembly for the custom control, and then click **OK**.

To add a custom control by using the command line

- To add a custom control, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/pages /+"controls.[assembly='*string***',namespace='***string***',src='***string***', tagName='***string***', tagPrefix='***string***']"**

  The variable **assembly** *string* is the name of the assembly that contains the COM control implementation and requires that the **namespace** attribute is also set. The variable **namespace** *string* is the namespace that is associated with the tag prefix and requires that the **assembly** attribute is also set, if the COM control is not located in the application code directory. The variable **src** *string* is the name of the file that contains the user control and requires that the **tagName** attribute is also set. The variable **tagName** *string* is the name of the control to use in the page and requires that the **src** attribute is also set. The variable **tagPrefix** *string* is the tag prefix that is being mapped to a source file or namespace and assembly. This attribute requires one of the following combinations of other attributes:

  - **namespace** to define a COM control, if the control is in the application code directory.
  - **namespace** and **assembly** to define a COM control.
  - **tagName** and **src** to define a user control.

  For example, to add a custom control that uses the specified source for a user control, type the following at the command prompt, and then press Enter:

  appcmd set config /commit:WEBROOT /section:system.web/pages /+"controls.[tagPrefix='MyTag', tagName='MyControl',src='controls/MyControl.asx']"

  Note
  When you use Appcmd.exe to configure the **<controls>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

2.3. Application Settings

This section describes how to configure application settings by using either the IIS Manager UI or the command line.

In Plan an ASP.NET Website on IIS, you made the following design decisions for each application setting you want to configure:

1. Specify a name for the setting.
2. Specify a value for the setting.

To create an application setting by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Application Settings**.
3. In the **Actions** pane, click **Add**.
4. In the **Add Application Setting** dialog box, type a name for the application setting in the **Name** text box.
5. In the **Add Application Setting** dialog box, type a value for the application setting in the **Value** text box, and then click **OK**.

To create an application setting by using the command line

- To add an application setting, use the following syntax:

  appcmd set config /commit:MACHINE /section:appSettings /+"[key='*string***',value='***string***']"**

  The variable **key** *string* is the name of the application setting and the variable **value** *string* is the value for the application setting. For example, to add an application setting for the name of your application, type the following at the command prompt, and then press Enter:

  appcmd set config /commit:MACHINE /section:appSettings /+"[key='Application Name',value='MyApplication']"

2.4. .NET Compilation Settings

Edit .NET compilation settings in IIS 8 when you want to control how ASP.NET code is compiled. This section describes how to edit the compilation settings for you ASP.NET application.

To configure .NET compilation settings by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **.NET Compilation**.
3. On the **.NET Compilation** page, edit settings as necessary.
4. When finished, click **Apply** in the **Actions** pane.

To configure .NET compilation settings by using the command line

- To enable or disable batch compilation for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /batch:True|False

  The variable **batch:True** enables batch compilation, and the variable **batch:False** disables batch compilation. The default value is **True**.
- To change the maximum file size (in KB) of the batch compilation, use the following syntax:

appcmd set config /commit:WEBROOT /section:compilation /maxBatchGeneratedFileSize:*int*

The variable *int* is the maximum file size (in KB). The default value is 1000.

- To specify the maximum number of pages per batched compilation for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /maxBatchSize:*int*

  The variable *int* is the maximum number of pages per batched compilation.

- To define the time-out period, in seconds, for batch compilation for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /batchTimeout:*timeSpan*

  The variable *int* is the maximum number of pages per batched compilation.

- To specify compilation of retail or debug binaries for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /debug:True|**False**

  The variable **debug:True** enables compilation of debug binaries and the variable **debug:False** enables compilation of retail binaries. The default value is **False**.

- To specify the number of times resources can be dynamically recompiled before an application restarts for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /numRecompilesBeforeAppRestart:*int*

  The variable *int* is the number of times resources are dynamically recompiled before the application is restarted. The default is 15.

- To enable or disable URL line pragma for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /urlLinePragmas:True|**False**

  The variable **urlLinePragmas:True** enables URL line pragma and the variable **urlLinePragmas:False** disables URL line pragma. The default value is **False**.

- To enable or disable Visual Basic explicit compilation for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /explicit:True|**False**

  The variable **explicit:True** enables Visual Basic explicit compilation and the variable **explicit:False** disables explicit compilation. The default value is **False**.

- To enable or disable Visual Basic strict compilation for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /strict:True|**False**

  The variable **strict:True** enables Visual Basic strict compilation and the variable **strict:False** disables strict compilation. The default value is **False**.

- To add an ASP.NET compilation processing directive for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /+"assemblies.[assembly='*string***']"**

  The variable *string* is the ASP.NET compilation processing directive.

- To remove an ASP.NET compilation processing directive for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /-"assemblies.[assembly='*string***']"**

  The variable *string* is the ASP.NET compilation processing directive.
- To remove an ASP.NET compilation processing directive for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /-"assemblies.[assembly='*string***']"**

  The variable *string* is the ASP.NET compilation processing directive.
- To change the default programming language that is used in dynamic compilation files for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /defaultLanguage:*string*

  The variable *string* is the default programming language. The default value is vb. For example, to change the default programming language that is used in dynamic compilation files from Visual Basic to C#, type the following at the command prompt, and then press Enter:

  appcmd set config /commit:WEBROOT /section:compilation /defaultLanguage:c#
- To specify the directory to use for temporary file storage during compilation for a site, use the following syntax:

  appcmd set config /commit:WEBROOT /section:compilation /tempDirectory:*string*

  The variable *string* is the directory path.

  Note
  When you use Appcmd.exe to configure the **<compilation>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

2.5. .NET Globalization Settings

This section describes how to edit the globalization settings for you ASP.NET application by using either the IIS Manager UI or the command line.

To edit .NET globalization settings by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **.NET Globalization**.
3. On the **.NET Globalization** page, in the property sheet, click to select the global setting you want to edit, and select a value from the drop-down list.

4. In the **Actions** pane, click **Apply**.

To edit .NET globalization settings by using the command line

- To edit the default culture for processing Web requests, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /culture:*string*

  The variable *string* is the default culture for processing web requests. For example, to change the default culture for processing Web requests to US English, type the following at the command prompt, and then press Enter:

  appcmd set config /commit:WEBROOT /section:globalization /culture:en-us

  Note
  When you use Appcmd.exe to configure the **<globalization>** element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To enable or disable client-based culture, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /enableClientBasedCulture:True|False

  The variable **enableClientBasedCulture:True** enables client-based culture and the variable **enableClientBasedCulture:False** disables client-based culture. The default is **False**.

- To edit the default culture for processing locale-dependent resource searches, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /uiCulture:*string*

  The variable *string* is the default culture for processing locale-dependent resource searches.

- To edit the default culture for processing locale-dependent resource searches, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /uiCulture:*string*

  The variable *string* is the default culture for processing locale-dependent resource searches.

- To change the default encoding when parsing .aspx, .asmx, and .asax files, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /fileEncoding:*string*

  The variable *string* is the default encoding to be used when parsing .aspx, .asmx, and .asax files.

- To change the header encoding for responses, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /responseHeaderEncoding:*string*

  The variable *string* is the header encoding used for responses. The default is utf-8.

- To edit the content encoding for responses, use the following syntax:

  appcmd set config /commit:WEBROOT /section:globalization /responseEncoding:*string*

  The variable *string* is the content encoding used for responses. The default is utf-8.

Step 3: Configure Data Source Settings

In this phase of building your ASP.NET website, you configure the data source settings that are available in IIS.

3.1. Data Source Connection Strings

3.2. ASP.NET Providers

3.3. .NET Profiles

3.4. .NET Roles

3.5. .NET Users

3.1. Data Source Connection Strings

This section describes how to create a database connection string in IIS using either the IIS Manager UI or the command line.

In Plan an ASP.NET Website on IIS, you made the following design decisions about the need to add a connection string:

1. Specify a name for the connection string.
2. Specify the server the database is on.
3. Specify the name of the database.
4. Provide the credentials, unless using Windows integrate security.

To create a database connection string by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Connection Strings**.
3. On the **Connection Strings** page, click **Add** in the **Actions** pane.
4. In the **Add Connection String** dialog box, type a name for the connection string, such as MyConnection, in the **Name** text box.

   Note

   The name that you enter in IIS Manager is the same name that you reference in your application code to retrieve data by using this connection string.
5. With the **SQL Server** option selected, type the name of the server that hosts the database in the **Server** text box and type the name of the database in the **Database** text

box.

6. Under **Credentials**:
   - Select **Use Windows Integrated Security**.

     -Or-
   - Select **Specify credentials** and click **Set**. Type a user name and password for an account that can connect to the server and database in the **User name** and **Password** text boxes. Then type the same password in the **Confirm password** text box, and click **OK**.
7. Click **OK**.

To create a database connection string by using the command line

- To create a database connection string, use the following syntax:

  appcmd set config /commit:MACHINE /section:connectionStrings /+"[connectionString='*string***',name='***string***',providerName='***string***']"**

  The variable **connectionString** *string* is the connection string value, the variable **name** *string* is the key to use to access the connection string value, and the variable **providerName** *string* is the name of the ADO.NET provider to use to access the underlying data store. For example, to create a connection string for an application that uses the Northwind database, type the following at the command prompt, and then press Enter:

  appcmd set config /commit:MACHINE /section:connectionStrings /+"[connectionString='Data Source=localhost;Integrated Security=SSPI;Initial Catalog=Northwind;',name='Northwind',providerName='System.Data.SqlClient ']"

3.2. ASP.NET Providers

This section describes how to add a .NET provider to IIS using either the IIS Manager UI or the command line.

In Plan an ASP.NET Website on IIS, you made the following design decisions about adding a .NET provider to IIS:

- Select the IIS feature for the provider to provide: .NET Profiles, .NET Roles, or .NET Users.
- Select the provider type.
- Enter a name for the provider.
- If the feature selected is .NET Users, select any of the following provider behaviors that you want:
  - Enable password reset
  - Enable password retrieval
  - Requires question and answer
  - Requires unique email
  - Store password in secure format

- Provide the name of the connection string to the database.
- Enter the name of the application.

To add a provider by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Providers**.
3. On the **Providers** page, under **Feature**, select one of the following features:
   - **.NET Roles**: to configure the provider to provide an interface between the ASP.NET role management service (the "role manager") and role data sources.
   - **.NET Users**: to configure the provider to provide an interface between the ASP.NET membership service and membership data sources.
   - **.NET Profile**: to configure the provider to provide an interface between the ASP.NET profile service and profile data sources.
4. In the **Actions** pane, click **Add**.
5. In the **Add Provider** dialog box, select a provider type from the **Type** drop-down list.
6. In the **Name** text box, type a name for the provider.
7. If the **.NET Users** feature was selected in step #3, in the **Profile properties** section, under **Behavior**, set the value of one or more of the following behaviors to **True** to enable the behavior:
   - **EnablePasswordReset**: indicates whether passwords can be reset by using the provider *ResetPassword* method. The default setting is **False**.
   - **EnablePasswordRetrieval**: indicates whether passwords can be retrieved by using the provider *GetPassword* method. The default setting is **False**.

     Important
     Some providers, such as the Active Directory provider, do not support the retrieval of passwords. For these providers, the value of the **enablePasswordRetrieval** attribute is always **False** and cannot be changed in configuration.
   - **RequiresQuestionAndAnswer**: indicates whether a password answer is supplied when the program calls the provider *GetPassword* and *ResetPassword* methods. The default setting is **False**.
   - **RequiresUniqueEmail**: indicates whether each registered user must have a unique e-mail address. The default setting is **False**.
   - **StorePasswordInSecureFormat**: indicates whether passwords are hashed. The default setting is **False**.
8. Under **Data**, type the name of the connection string that is used to connect to the database in the **ConnectionStringName** text box.

   Note
   This is the same connection string that was configured under the **Connection Strings** feature. For more information about how to configure connection strings,

see **Configuring database connection strings**. If the *WindowsTokenRoleProvider* was selected in step #5 of this procedure, a connection string name is optional.

9. Optionally, in the **Profile properties** section, under **General**, type the virtual path of the application in the **ApplicationName** text box. If you do not specify a value in the **ApplicationName** text box, the membership API defaults to HttpContext.Current.Request.ApplicationPath. This path can be determined only at runtime.
10. Optionally, in the **Profile properties** section, under **General**, type a description of the provider in the **Description** text box.
11. Click **OK**.

To add a provider by using the command line

1. To add a .NET role provider, use the following syntax:

   appcmd set config /commit:MACHINE /section:roleManager /+"providers.[name='*string***',type='***string***',connectionStringName='***string***',applicationName='***string***']"**

   The variable **name** *string* is the name of the provider. The variable **type** *string* is the provider type. The variable **connectionStringName** *string* is the name of the connection string that is used to connect to the database. The variable **applicationName** *string* is optional and is the virtual path of the application. For example, to configure an ASP.NET application to use the **SqlRoleProvider** class to store and retrieve role information, type the following at the command prompt, and then press Enter:

   appcmd set config /commit:MACHINE /section:roleManager /+"providers.[name='SqlProvider',type='System.Web.Security.SqlRoleProvider',connectionStringName='SqlServices',applicationName='SampleApplication']"
2. To add a .NET user provider, use the following syntax:

   appcmd set config /commit:MACHINE /section:membership /+"providers.[name='*string***',type='***string***',connectionStringName='***string***',applicationName='***string***',enablePasswordReset='True|False',enablePasswordRetrieval='True|False',requiresQuestionAndAnswer='True|False',requiresUniqueEmail='True|False',storePasswordInSecureFormat='True|False']"**

   The variable **name** *string* is the name of the provider. The variable **type** *string* is the provider type. The variable **connectionStringName** *string* is the name of the connection string that is used to connect to the database. The variable **applicationName** *string* is optional and is the virtual path of the application. The variable **enablePasswordReset True** enables password reset by using the provider *ResetPassword* method. The default setting is **False**. The variable **enablePasswordRetrieval True** enables password retrieval by using the provider *GetPassword* method. The default setting is **False**. The variable **requiresQuestionAndAnswer True** requires that a password answer must be supplied when the program calls the provider *GetPassword* and *ResetPassword* methods. The

default setting is **False**. The variable **requiresUniqueEmail True** requires that each registered user has a unique e-mail address. The default setting is **False.** The variable **storePasswordInSecureFormat True** requires that all passwords must be hashed. The default setting is **False**. For example, to configure an ASP.NET application to use the **SqlMembershipProvider** class to store and retrieve user information, type the following at the command prompt, and then press Enter:

appcmd set config /commit:MACHINE /section:membership /+"providers.[name='SqlProvider',type='System.Web.Security.SqlMembershipProvider',connectionStringName='SqlServices',applicationName='/',enablePasswordRetrieval='False',enablePasswordReset='True',requiresQuestionAndAnswer='True']"

3. To add a .NET profile provider, use the following syntax:

   appcmd set config /commit:MACHINE /section:profile /+"providers.[name='*string***',type='***string***',connectionStringName='***string***',applicationName='***string***']"**

   The variable **name** *string* is the name of the provider. The variable **type** *string* is the provider type. The variable **connectionStringName** *string* is the name of the connection string that is used to connect to the database. The variable **applicationName** *string* is optional and is the virtual path of the application. For example, to configure an ASP.NET application to use the **SqlProfileProvider** class to store and retrieve profile information, type the following at the command prompt, and then press Enter:

   appcmd set config /commit:MACHINE /section:profile /+"providers.[name='SqlProvider',type='System.Web.Profile.SqlProfileProvider',connectionStringName='SqlServices',applicationName='SampleApplication']"

3.3. .NET Profiles

This section describes how to add a profile property and a profile group.

In Plan an ASP.NET Website on IIS, you made the following design decisions about profile properties and groups to IIS:

- For each profile property, provide the property name, data type (such as string or Boolean), a default value, a serialization option (string, XML, binary, or provider specific), whether it is read-only, and whether it is available for anonymous users.
- For each profile group, provide the group name.

To add a .NET profile property by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **.NET Profile**.
3. In the **Actions** pane, click **Add Property** to add a .NET profile property or, to add a .NET profile property to a group, select the group to which you want to add the .NET profile property, and then click **Add Property To Group**.
4. In the **Add .NET Profile Property** dialog box, type a name for the .NET profile property

in the **Name** text box.

5. Under **Data Type**, select one of the following data types:
   - **System.Boolean**: to configure the .NET profile property to have a value of either **True** or **False**.
   - **System.Char**: to configure the .NET profile property to contain Unicode Characters.
   - **System.DateTime**: To configure the .NET profile property to contain dates and times with values that range from 12:00:00 midnight, January 1, 0001 Anno Domini (A.D.) or Common Era (C.E.) through 11:59:59 P.M., December 31, 9999 A.D. (C.E.)
   - **System.Decimal**: to configure .NET profile property to contain decimal numbers that range from positive 79,228,162,514,264,337,593,543,950,335 to negative 79,228,162,514,264,337,593,543,950,335. The **Decimal** value type is appropriate for financial calculations that require many significant integral and fractional digits and no round-off errors.
   - **System.Double**: To configure the .NET profile property to contain a double-precision 64-bit number with values that range from negative 1.79769313486232e308 to positive 1.79769313486232e308, as well as positive or negative zero, **PositiveInfinity**, **NegativeInfinity**, and Not-a-Number (NaN). For more information about the **Double** value type, see Double Structure.
   - **System.Int32**: to configure the .NET profile property to contain a signed integer with a value that ranges from negative 2,147,483,648 through positive 2,147,483,647.
   - **System.Int64**: to configure the .NET profile property to contain an integer with a value that ranges from negative 9,223,372,036,854,775,808 through positive 9,223,372,036,854,775,807.
   - **System.Single**: To configure the .NET profile property to contain a single-precision 32-bit number with values that range from negative 3.402823e38 to positive 3.402823e38, as well as positive or negative zero, **PositiveInfinity**, **NegativeInfinity**, and Not-a-Number (NaN). For more information about the **Single** value type, see Single Structure.
   - **System.String**: To configure the .NET profile property to be a sequential collection of **Char** structures that represents a string of text. This setting is the default.
6. In the **Default value** text box, type a value that the property will be initialized with.
7. Under **Serialization option**, select one of the following serialization formatters:
   - **String**: Select this option when the settings property is serialized as plaintext. This setting is the default.
   - **XML**: Select this option to serialize only public properties and fields. XML serialization does not preserve type fidelity. This option is useful when you want to provide or consume data without restricting the application that uses the data. Because XML is an open standard, it is an attractive choice for sharing data on the Web.
   - **Binary**: Select this option to preserve type fidelity. Binary serialization is useful for preserving the state of an object between different invocations of an application. For example, you can share an object between different applications by serializing it to the Clipboard. You can serialize an object to a stream, to a disk, to memory, over the network, and so on.

- **Provider Specific**: Select this option when the settings provider has implicit knowledge of the property or its type and can pick an appropriate serialization mechanism. This option is often used for custom serialization.

8. Check the **Read only** box to configure the .NET profile property so that it cannot be modified.
9. Check the **Available for anonymous users** box to make the .NET profile property available for unauthenticated users.
10. Click **OK**.

To add a .NET profile property by using the command line

- To add a .NET Profile property, use the following syntax:

  appcmd set config /commit:MACHINE /section:profile /+"properties.[name='*string*',type='*string*',defaultValue='*string*',serializeAs='String|Xml|Binary|ProviderSpecific',readOnly='True|False',allowAnonymous='True|False']"

  The variable **name** *string* is the name of the profile property. The variable **type** *string* is the data type. The variable **defaultValue** *string* is the value with which the profile property is initialized. The variable **serializeAs 'String|Xml|Binary|ProviderSpecific** sets the serialization formatter. The variable **readOnly True** configures the .NET profile property so that it cannot be modified. The default value is **False**. The variable **allowAnonymous True** makes the .NET profile property available for unauthenticated users. The default value is **False**. For example, to specify a profile property that holds a recent search list collection, type the following at the command prompt, and then press Enter:

  appcmd set config /commit:MACHINE /section:profile /+"properties.[name='RecentSearchList',type='System.Collections.Specialized.StringCollection',serializeAs='Xml',allowAnonymous='true']"

To add a .NET profile group by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **.NET Profile**.
3. In the **Actions** pane, click **Add Group**.
4. In the **Add Group** dialog box, type a name for the .NET profile group in the **Name** text box, and then click **OK**.

3.4. .NET Roles

This section describes how to add a .NET role by using the IIS Manager UI.

To add a .NET role by using the UI

1. Open IIS Manager and navigate to the level you want to manage.

2. In **Features View**, double-click **.NET Roles**.
3. In the **Actions** pane, click **Add**.
4. In the **Add .NET Role** dialog box, type the name of the role in the **Name** text box, and then click **OK**.

3.5. .NET Users

This section describes how to configure .NET users by using the IIS Manager UI.

In Plan an ASP.NET Website on IIS, you made the following design decisions for each user you want to add to IIS:

- User Name
- E-mail
- Password
- Question
- Answer
- Role or roles

To add a .NET user by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **.NET Users**.
3. In the **Actions** pane, click **Add**.
4. In the **.NET User Account Details** dialog box, enter the following information:
   - User Name (must be unique).
   - E-mail (must use standard format: name@domain.com).
   - Password (must be a strong password).
   - Confirm Password (must match the password).
   - Question (enter a custom question or select from the list).
   - Answer to the question.
5. Click **Next** to select roles for this user. If you have not enabled **.NET Roles**, click **Finish**.
6. In the **.NET User Roles** dialog box, optionally select available roles from the **Roles** box, and then click **Finish**.

Step 4: Configure Application Security

In this phase of building your ASP.NET website, you configure the security settings that are available in IIS. The following sections discuss common security settings for ASP.NET applications:

4.1. Isolate Web Applications
4.1. .NET Trust Levels
4.2. .NET Authentication
4.3. Machine Key Settings
4.4. TLS/SSL Communication

4.1. Isolate Web Applications

Implement the following recommendations to isolate websites and web applications on your server.

- Use one application pool per website or web application.
- Limit access to site folders and files to the application pool identity.
- Set up a separate ASP.NET temp folder per site and only give access to the application pool identity.
- Make sure to set an ACL (access control list) on each site root to allow only access to the application pool identity.

If you have more than one application per application pool, consider creating enough application pools and moving some of the applications to the new pools.

To create an application pool

1. Open IIS Manager.
2. In the **Connections** pane, click **Application Pools**.
3. In the **Actions** pane, click **Add Application Pool**.
4. In the **Name** box, type a unique name for the application pool.
5. Select the **.NET Framework version** and **Managed pipeline mode**.
6. Click **OK**.

To move an application to another application pool

1. Open IIS Manager.
2. In the **Connections** page, select the website or web application you want to move.
3. In the **Actions** pane, click **Basic Settings**.
4. On the **Edit Site** dialog, click **Select** to open the **Select Application Pool** dialog, and then select the application pool from the **Application pool** menu.
5. Click **OK** to close the **Select Application Pool** dialog, and click **OK** to close the **Edit Site** menu.

To add an application pool identity to a folder or file ACL

1. Open Windows Explorer and navigate to the folder or file.
2. Right click the folder or file, and then click **Properties**.

3. Select the **Security** tab, and then click **Edit**.
4. Click **Add**, click **Locations**, and select your server as the location to search.
5. In the **Enter the object names to select** box, type **IIS APPPOOL\applicationPoolName**, where *applicationPoolName* is the application pool identity.
6. Click **OK**, click **OK**, and click **OK** again to close the dialogs.

4.1. .NET Trust Levels

This section describes how to set application trust level by using either IIS Manager UI or the command line.

To set a trust level by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **.NET Trust Levels**.
3. On the **.NET Trust Levels** page, select a trust level from the **Trust level** drop-down list, and then click **Apply** in the **Actions** pane.

To set a trust level by using the command line

1. To set a trust level, use the following syntax:

   appcmd set config /commit:WEBROOT /section:trust /level: Full | High | Medium | Low | Minimal

   The level attribute uses one of five values that correspond to preconfigured CAS policy files. For example, to set a trust level of **Full**, type the following at the command prompt, and then press ENTER:

   appcmd set config /commit:WEBROOT /section:trust /level:Full

   Note
   When you use Appcmd.exe to configure the trust element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

4.2. .NET Authentication

In Plan an ASP.NET Website on IIS, you made design decisions about what authentication mode was right for your application. The following sections decide how to configure authentication for your ASP.NET application:

1. ASP.NET Forms Authentication
2. ASP.NET Impersonation Authentication

ASP.NET Forms Authentication

This section describes how to configure ASP.NET forms authentication by using either the IIS Manager UI or the command line.

To configure forms authentication by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Authentication**.
3. On the **Authentication** page, select **Forms Authentication**.
4. In the **Actions** pane, click **Enable** to use Forms authentication with the default settings.
5. In the **Actions** pane, click **Edit**.
6. In the **Edit Forms Authentication Settings** dialog box, in the **Login URL** text box, type the name of the page where clients log in.
7. In the **Authentication cookie time-out (in minutes)** text box, type the number of minutes you want to use for the time-out value.
8. From the **Mode** list, select the cookie mode you want to use.
9. In the **Name** text box, type the name of the cookie.
10. From the **Protection mode** list, select the protection mode you want to use.
11. Select the **Requires SSL** check box.
12. Select the **Extend cookie expiration on every request** check box, and then click **OK**.

To configure forms authentication by using the command line

- To enable forms authentication, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /mode: None | Windows | Windows Live ID | Forms

  By default, IIS 8 sets the **mode** attribute to Windows, which disables Forms authentication. If you set the attribute to Forms, you enable Forms authentication. For example, to enable Forms authentication, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /mode:Forms

  Note
  When you use Appcmd.exe to configure the authentication element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To specify the login URL for Forms authentication, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.loginURL:*string*

The variable **forms.loginURL** *string* is the name of the page where clients login. The default value is Login.aspx. For example, to specify the login URL for Forms authentication, type the following at the command prompt, and then press ENTER:

appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.loginURL:login.aspx

Note

When you use Appcmd.exe to configure the authentication element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To specify the authentication time-out for Forms authentication, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.timeout:*TimeSpan*

  The variable **forms.timeout** *TimeSpan* is the time in minutes when the cookie used for authentication expires. The default value is 30 minutes. For example, to specify the authentication time-out for Forms authentication, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.timeout:30

  Note

  When you use Appcmd.exe to configure the authentication element at the global level in IIS 8, you must specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

- To configure the cookie name for Forms authentication, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.name:*string*

  The variable **forms.name** *name* is the name of the cookie used for Forms authentication. The default value is .ASPXAUTH. For example, to configure the cookie name for Forms authentication, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.name:.ASPXUTH

- To configure the cookie mode for Forms authentication, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.cookieless: UseUri | UseCookies | AutoDetect | UseDeviceProfile

  The default value for **forms.cookieless** is **UseDeviceProfile**. For example, to configure the cookie mode for Forms authentication to use the setting Use Device Profile, type the

following at the command prompt, and then press ENTER:

appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.cookieless:UseDeviceProfile

- To configure the cookie protection mode for Forms authentication, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.protection: All | None | Encryption | Validation

  The default value for **forms.protection** is **All**. For example, to configure the cookie protection mode for Forms authentication to use the setting Encryption and Validation, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.protection:All

- To require SSL for an authentication cookie, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.requireSSL: True | False

  The default value for **forms.requireSSL** is False. If you set this attribute to **True**, you require SSL. For example, to require SSL for an authentication cookie, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.requireSSL:True

- To cache frequently requested content, use the following syntax:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.slidingExpiration: True | False

  The default value for **forms.slidingExpiration** is **True**. For example, to cache frequently requested content, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:system.web/authentication /forms.slidingExpiration:True

ASP.NET Impersonation Authentication

To configure Impersonation Authentication by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Authentication**.
3. On the **Authentication** page, select **ASP.NET Impersonation**.
4. In the **Actions** pane, click **Enable** to use ASP.NET Impersonation authentication with the

default settings.

5. Optionally, in the **Actions** pane, click **Edit** to set the security principal.
6. In the **Edit ASP.NET Impersonation Settings** dialog box, select either **Specific user** or **Authenticated user**. Whichever you decide, IIS uses this identity for the security context of the ASP.NET application. By default, IIS 8 is set to impersonate the authenticated user.
7. Click **OK** to finish or proceed to the next optional steps to change the identity to impersonate.
8. Optionally, click **Set** to change the **Specific user** identity.
9. In the **Set Credentials** dialog box, enter the name of an existing user account in **User name,** the password associated with that user account in **Password**, and then the exact same value in **Confirm password** for a new account IIS should use for anonymous access.
10. Click **OK** to close the **Set Credentials** dialog box.
11. Click **OK** to close the **Edit ASP.NET Impersonation Settings** dialog box.

To configure Impersonation Authentication by using the command line

- To enable or disable ASP.NET Impersonation, use the following syntax:

  appcmd set config /commit:WEBROOT /section:identity /impersonate:true | **false**

  By default, IIS sets the **impersonate** attribute to false, which disables ASP.NET Impersonation authentication. If you set the attribute to true, you enable ASP.NET Impersonation authentication. For example, to enable ASP.NET Impersonation authentication, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:identity /impersonate:true

- Optionally, you can set the account for IIS to impersonate, using the following syntax:

  appcmd set config /commit:WEBROOT /section:identity /userName:*string* **/password:***string*

  The variable **userName** *string* is the account IIS uses to impersonate and the variable **password** *string* is the password. For example, to use an account named **Moe** for IIS to impersonate, type the following at the command prompt, and then press ENTER:

  appcmd set config /commit:WEBROOT /section:identity /userName:Moe /password:pass@word1

  Note

  When you use Appcmd.exe to configure the identity element at the global level in IIS 8, specify **/commit:WEBROOT** in the command so that configuration changes are made to the root Web.config file instead of ApplicationHost.config.

4.3. Machine Key Settings

This section describes how to generate machine keys for your ASP.NET application by using the IIS Manager UI.

To generate machine keys by using the UI

1. Open IIS Manager and navigate to the level you want to manage.
2. In **Features View**, double-click **Machine Key**.
3. On the **Machine Key** page, select a validation method from the **Validation method** list. The default validation method is **SHA1**.
4. Choose an encryption method from the **Encryption method** list. The default encryption method is **Auto**.
5. Optionally, configure settings for validation and decryption keys.
6. In the **Actions** pane, click **Generate Keys**, and then click **Apply**.

4.4. TLS/SSL Communication

This section describes how to configure TLS/SSL security for your application.

After obtaining a server certificate from a certification authority (CA), work through the procedures in the following sections:

1. SSL Binding
2. Require SSL for Your Site
3. Client Certificates

SSL Binding

This section describes how to add an SSL binding to your site by using either the IIS Manager UI or the command line.

To add an SSL binding to a site

1. Open IIS Manager.
2. In the **Connections** pane, expand the **Sites** node in the tree, and then click to select the site for which you want to add a binding.
3. In the **Actions** pane, click **Bindings**.
4. In the **Site Bindings** dialog box, click **Add**.
5. In the **Add Site Binding** dialog box, in the **Type** list, select **https**.
6. From the **IP address** list, select **All Unassigned** (unless there is a specific IP address you want to use).
7. In the **Port** box, type the number of the port (the default is 443).
8. In the **Host name** box, type the name of the host computer.
9. If you want multiple secure websites to be served using the same IP address, select the

Require Server Name Indication check box.

10. From the **SSL certificate** list, select the certificate for your website. If your certificate doesn't appear in the list, click **Select** and search for the certificate using the **Select Certificate** dialog box.
11. Click **OK**.

1. To add a binding to a site, use the following syntax:

   appcmd set site /site.name:*string* **/+bindings.[protocol='***string***',bindingInformation='***string***']**

   The variable **site.name** *string* is name of the site to which you want to add a binding. The variable **protocol** *string* is the protocol that you want to use, and the variable **bindingInformation** *string* is the combination of IP address, port, and host header.

   For example, to configure a site named **contoso** to have an HTTPS binding for all IP addresses, on port 443, without a host header, type the following at the command prompt, and then press ENTER:

   appcmd set site /site.name:contoso /+bindings.[protocol='https',bindingInformation='*:443:']

Require SSL for Your Site

This section describes how to require SSL for your website by using the IIS Manager UI or the command line.

To require SSL using the UI

1. Open IIS Manager and navigate to the level you want to manage.

   Make sure that you are at the site, application, or directory level; **SSL Settings** are not available at the server level.

   Note
   If you want to configure SSL at the file level, navigate to the file in **Content View** and then click **Switch to Features View** in the **Actions** pane.
2. In **Features View**, double-click **SSL Settings**.
3. On the **SSL Settings** page, select **Require SSL**.
4. In the **Actions** pane, click **Apply**.

To require SSL using the command line

- To require SSL, use the following syntax:

  appcmd set config "*site* | *URL***" /section:access /sslFlags:Ssl /commit:APPHOST**

  The variable *site* | *URL* is the site, application, virtual directory, or file where you want IIS 8 to require SSL. For example, to require SSL for the Default Web Site, type the following

at the command prompt, and then press ENTER:

appcmd set config "Default Web Site" /section:access /sslFlags:Ssl /commit:APPHOST

- To require SSL for the file iisstart.htm on the Default Web Site, type the following at the command prompt, and then press ENTER:

  appcmd set config "http://localhost/iisstart.htm" /section:access /sslFlags:Ssl /commit:APPHOST

Client Certificates

This section describes how to

To specify client certificates by using the UI

1. Open IIS Manager and navigate to the level you want to manage.

   Make sure that you are at the site, application, or directory level; **SSL Settings** are not available at the server level.

   Note
   If you want to configure SSL at the file level, navigate to the file in **Content View** and then click **Switch to Features View** in the **Actions** pane.
2. In **Features View**, double-click **SSL Settings**.
3. On the **SSL Settings** page, optionally select **Require SSL**. You do not need SSL to **Ignore** or **Accept** client certificates.
4. On the **SSL Settings** page, in the **Client certificates** area, use one of the following procedures:
   - Select **Ignore** if you do not want to accept a client certificate even if a client presents one.
   - Select **Accept** to accept client certificates.
   - Select **Require** to require client certificates. To use **Require Client Certificates**, you must enable **Require SSL**.
5. In the **Actions** pane, click **Apply**.

To specify client certificates by using the command line

- To specify whether to use client certificates, use the following syntax:

  appcmd set config "*site* | *URL***"/section:access /sslFlags: Ssl | SslNegotiateCert | SslRequireCert /commit:APPHOST**

  The variable *site* | *URL* is the site, application, virtual directory, or file where you want IIS to enable client certificates. For example, to accept client certificates for the Default Web Site, type the following at the command prompt, and then press ENTER:

  appcmd set config "Default Web Site"/section:access /sslFlags:SslNegotiateCert /commit:APPHOST

- To accept client certificates for the file iisstart.htm on the Default Web Site, type the following at the command prompt, and then press ENTER:

  appcmd set config "http://localhost/iisstart.htm"/section:access /sslFlags:SslNegotiateCert /commit:APPHOST

  You can specify one or more of the values for the sslFlags attribute. If you want more than one value, separate each value with a comma (,). For example, to specify a requirement for both SSL and client certificates on the Default Web Site, type the following at the command prompt, and then press ENTER:

  appcmd set config "Default Web Site"/section:access /sslFlags:Ssl,SslRequireCert /commit:APPHOST

Build an FTP Site on IIS

File Transfer Protocol (FTP) simple is a protocol for transferring files between computer systems. IIS 8 includes an FTP server that is easy to configure.

The document shows how to install and configure the FTP server on an existing IIS 8 web server. The first two steps are required. All other steps are optional but recommended.

In this document

- Prerequisites
- Step 1: Install FTP on an Existing IIS Web Server
- Step 2: Add an FTP Site
- Step 3: Configure FTP Site Defaults
- Step 4: Configure Firewall Support
- Step 5: Configure User Isolation
- Step 6: Configure Directory Browsing Options
- Step 7: Configure Logon Attempt Restrictions
- Step 8: Configure Request Filtering
- Step 9: Configure FTP Logging
- Step 10: Configure FTP Messages

Prerequisites

To get the most from this tutorial, you must have access to a computer that runs one of the following operating systems:

- Windows Server® 2012
- Windows® 8

Step 1: Install FTP on an Existing IIS Web Server

This step shows you how to install the FTP service on an existing IIS web server that runs on either Windows Server 2012 or Windows 8.

To install FTP on Windows Server 2012

1. On the **Start** screen, click the **Server Manager** tile, then click **Yes**.
2. In the **Server Manager Dashboard**, click **Add roles and features**.
3. If the **Before you begin** page of **Add Roles and Features Wizard** is displayed, click **Next**.
4. On the **Select installation type** page, select **Role-based or feature-based installation**, and click **Next**.
5. On the **Select destination server** page, select **Select a server from the server pool**, select your server from the **Server Pool** list, and then click **Next**.
6. On the **Select server roles** page, expand the **Web Server (IIS)** node, and then expand the **FTP Server** node.
7. Select the **FTP Server** check box and the **FTP Service** check box, and then click **Next**.
8. On the **Select features** page, click **Next**.
9. On the **Confirm installation selections** page, click **Install**.

To install FTP on Windows 8

1. On the **Start** screen, type **Control Panel**, and then click the **Control Panel** icon in the search results.
2. Click **Programs**, and then click **Turn Windows features on or off**.
3. In the **Windows Features** dialog box, expand the **Internet Information Services** node.
4. Expand the **FTP Server** node.
5. Select the **FTP Server** check box and the **FTP Service** check box, and then click **OK**.

Step 2: Add an FTP Site

Once the FTP service is installed on your IIS web server, you can add one or more FTP sites. Add an FTP site when you want to enable clients to transfer files to and from a site by using the File Transfer Protocol (FTP).

Note

Because FTP settings are contained in the sites section, changing any FTP setting also forces website application recycling. If you want to avoid this side effect, add a site that is configured exclusively for FTP, instead of for both HTTP and FTP.

To add an FTP site

1. Open IIS Manager.

2. In the **Connections** pane, expand the server node and click the **Sites** node.
3. In the **Actions** pane, click **Add FTP Site** to open the **Add FTP Site** wizard.
4. On the **Site Information** page, in the **FTP site name** box, type a unique friendly name for the FTP site.
5. In the **Physical path** box, type the physical path or click the browse button (**...**) to locate the physical path of the content directory.
6. Click **Next** to open the **Binding and SSL Settings** page.
7. Under **Binding**, in the **IP Address** list, select or type an IP address if you do not want the IP address to remain **All Unassigned**.
8. In the **Port** box, type the port number.
9. Optionally, in the **Virtual Host** box, type a host name if you want to host multiple FTP sites on a single IP address. For example, type **www.contoso.com**.
10. Clear the **Start FTP site automatically** box if you want to start the site manually.
11. Under **SSL**, from the **SSL Certificate** list, select a certificate. Optionally, click **View** to open the **Certificates** dialog box and verify information about the selected certificate.
12. Select one of the following options:
    - **Allow SSL**: Allows the FTP server to support both non-SSL and SSL connections with a client.
    - **Require SSL**: Requires SSL encryption for communication between the FTP server and a client.
13. Click **Next** to open the **Authentication and Authorization Information** page.
14. Under **Authentication**, select the authentication method or methods that you want to use:
    - **Anonymous**: Allows any user to access content providing only the user name **anonymous** or **ftp**. (Most, but not all, FTP clients enter user name for you automatically.)
    - **Basic**: Requires users to provide a valid user name and password to access content. Because Basic authentication transmits unencrypted passwords across the network, use this authentication method only when you know that the connection between the client and FTP server is secure, such as by using Secure Sockets Layer (SSL).
15. Under **Authorization**, from the **Allow access to** list, select one of the following options:
    - **All Users**: All users, whether they are anonymous or identified, can access the content.
    - **Anonymous Users**: Anonymous users can access the content.
    - **Specified Roles or User Groups**: Only members of certain roles or user groups can access the content. Type the role or user group in the corresponding box.
    - **Specified Users**: Only specified users can access the content. Type the user name in the corresponding box.
16. If you selected an option from the **Allow access to** list, select one or both of the following permissions:
    - **Read**: Permits authorized users to read content from the directory.

- **Write**: Permits authorized users to write to the directory.

17. Click **Finish**.

Step 3: Configure FTP Site Defaults

Change an FTP site default value when you want new FTP sites to use a different default value.

Note

When you change a default value, existing sites are not overridden with the new value. Change the value for any existing sites manually.

To configure FTP site defaults

1. Open IIS Manager.
2. In the **Connections** pane, click the server node and the **Sites** node.
3. In the **Actions** pane, click **FTP Site Defaults**.
4. Edit the settings, and then click **OK**.

The following table lists the settings available for configuration in the **FTP Site Defaults** dialog box.

Setting Category	Setting Name	Description
General	Allow UTF-8	Specifies whether to use UTF8 encoding. Default is true.
General	Start Automatically	If true, the FTP site is started upon creation or when the FTP service is started. Default is true.
Connections	Control Channel Time-out	Specifies the time-out (in seconds) when a connection times out due to inactivity.
Connections	Data Channel Time-out	Specifies the time-out (in seconds) when the data channel times out due to inactivity.
Connections	Disable Socket Pooling	Specifies whether socket pooling is used for sites distinguished by IP address rather than port number or host name.
Connections	Max Connections	Specifies the maximum

Setting Category	Setting Name	Description
		simultaneous connections to a server.
Connections	Reset On Max Connections	Specifies whether to disconnect FTP session when sending max connections response.
Connections	Server Listen Backlog	Specifies the number of outstanding sockets that can be queued.
Connections	Unauthenticated Time-out	Specifies the timeout (in seconds) between when a new connection is made and authentication succeeds.
Credential Caching	Enabled	Specifies whether credential caching is enabled for the FTP service.
Credential Caching	Flush Interval	Specifies the cache lifetime, in seconds, for the credentials that are stored in the cache.
File Handling	Allow Reading Files While Uploading	Specifies whether files can be read while being transferred to the server.
File Handling	Allow Replace on Rename	Specifies whether files can overwrite other files when renamed.
File Handling	Keep Partial Uploads	Specifies whether to keep files that have been partially uploaded.

Step 4: Configure Firewall Support

Use the **FTP Firewall Support** feature to configure the following settings that enable the FTP server to accept passive data connections from a firewall:

- **Data Channel Port Range**: Specify a range of ports for passive data connections. You must also open that same range of ports on your firewall. This option can only be configured at the server-level, and the port range of “0-0” means to use the ephemeral port range of the server.

An ephemeral port is a short-lived transport protocol port that TCP/IP allocates from a predefined range.

- **External IP Address of Firewall**: Specify the external IP address of your firewall so that clients know which IP address to use when they communicate with the FTP server through the firewall.

To configure firewall support

1. Open IIS Manager.
2. In the **Connections** pane, select the server node.
3. In **Features View**, double-click **FTP Firewall Support**.
4. In the **Data Channel Port Range** box, type a range of port numbers (separated by a hyphen). For example, type **5000-6000**. Or type **0-0** to use the default port range specified in Windows TCP/IP settings.

   Note
   Do not use ports 0-1024 because these ports are reserved ports.
5. In the **External IP Address of Firewall** box, type the IP address of your firewall.
6. In the **Actions** pane, click **Apply**.

Step 5: Configure User Isolation

The user isolation feature allows you to configure your FTP server to isolate users, which prevents users from accessing the directories of other users on the same FTP site. If you choose not to isolate users, they share a common directory structure.

For example, you can choose not to isolate users on a site that offers only download capabilities for shared content or for a site that does not require the protection of data between users.

If you want to isolate users on your site, you can choose one of the following isolation options:

1. **User name directory**: Isolates user sessions to the physical or virtual directory with the same name of the FTP user account. The user sees only their FTP root location and is, therefore, restricted from navigating higher up the physical or virtual directory tree. Any global virtual directories that are created are ignored.
2. **User name physical directory**: Isolates user sessions to the physical directory with the same name of the FTP user account. The user sees only their FTP root location and is, therefore, restricted from navigating higher up the physical directory tree. Any global virtual directories that are created apply to all users.
3. **FTP home directory configured in Active Directory**: Isolates user sessions to the home directory that is configured in the Active Directory account settings for each FTP user.

To configure user isolation

1. Open IIS Manager.
2. In **Features View**, double-click **FTP User Isolation**.

3. If you don't want to isolate users, under **Do not isolate users. Start users in**, select one of the following options:
   - **FTP root directory**: specifies that all FTP sessions start in the root directory for the FTP site. This option disables all user isolation and starting folder logic.
   - **User name directory**: specifies that all FTP sessions start in the physical or virtual directory with the same name of the currently logged-on user if the folder exists; otherwise, the FTP session starts in the root directory for the FTP site.
4. If you want to isolate users, under **Isolate users. Restrict users to the following directory**, select one of the following options:

   User name directory (disable global virtual directories): isolates user sessions to the physical or virtual directory with the same name of the FTP user account.

   User name physical directory (enable global virtual directories): isolates user sessions to the physical directory with the same name of the FTP user account.

   FTP home directory configured in Active Directory: isolates user sessions to the home directory that is configured in the Active Directory account settings for each FTP user.

   Custom: This option is an advanced feature, and enables developers to create custom providers that provide home directory lookups based on their unique business needs.
5. If you selected **FTP home directory configured in Active Directory** in the previous step, click the **Set** button, and then type a user name and password in the **User name** and **Password** boxes of the **Set Credentials** dialog box that has access to your Active Directory server. Enter the password again in the **Confirm Password** box, then click **OK**.
6. In the **Actions** pane, click **Apply**.

Step 6: Configure Directory Browsing Options

The directory browsing feature gives you control over what is displayed when users browse FTP directories.

To configure directory browsing options

1. Open IIS Manager.
2. In the **Connections** pane, select either the server level or the site level.
3. In **Features View**, double-click **FTP Directory Browsing**.
4. On the **FTP Directory Browsing** page, under **Directory Listing Style**, select one of the following options:
   - **MS-DOS**: Displays directory content in a manner consistent with MS-DOS.
   - **UNIX**: Displays directory content in a manner consistent with UNIX.
5. Under **Directory Listing Options**, select the information you want to display in directory listings. You can select any of the following options:
   a. **Virtual directories**: Shows virtual directories.
   b. **Available bytes**: Displays file size in bytes.

c. **Four-digit years**: Displays years by using four digits rather than two.

6. In the **Actions** pane, click **Apply**.

Step 7: Configure Logon Attempt Restrictions

This feature enables you to configure the maximum number of failed sign-on attempts that you allow within a specified time before the IP address is denied.

To configure logon attempt restrictions

1. Open IIS Manager.
2. In the **Connections** pane, select the server level.
3. In **Features View**, double click **FTP Logon Attempt Restrictions**.
4. On the **FTP Logon Attempt Restrictions** page, select the **Enable FTP Logon Attempt Restrictions** check box.
5. In the **Maximum number of failed login attempts** box, type a positive integer. The default value is 4.
6. In the **Time period (in seconds)** box, type a positive integer. The default is 30.
7. Select either **Deny IP addresses based on the number of failed login attempts** or **Write to the log only**. If you choose **Write to the log only**, IIS will not restrict clients even if the maximum number of failed attempts is exceeded.
8. In the **Actions** page, click **Apply**.

Step 8: Configure Request Filtering

Use the **FTP Request Filtering** feature page to define the request filtering settings for your FTP site. FTP request filtering is a security feature that allows internet service providers (ISPs) and application service providers to restrict protocol and content behavior.

To configure request filtering

1. Open IIS Manager.
2. In the **Connections** pane, select either the server level or the site level.
3. In **Feature View**, double click the **FTP Request Filtering** icon.
4. To change the general request filtering settings, click **Edit Feature Settings** in the **Actions** pane. Then edit the general settings as required.
5. To add a filter based on file name extensions, select the **File Name Extension** tab. In the **Actions** pane, click either **Allow File Name Extension** or **Deny File Name Extensions**. Then type the extension in the **File name extension** box, and click **OK**.
6. To add a filter based on a URL segment (for example, a folder name), select the **Hidden Segments** tab. In the Actions pane, click **Add Hidden Segment**. Then type the segment in the **Hidden segment** box, and click **OK**.
7. To add a filter based on a URL sequence, select the **Denied URL Sequences** tab. In the

Actions pane, click **Add URL Sequence**. Then type the sequence in the **URL sequence** box, and click **OK**.

8. To add a filter based on a command, select the **Commands** tab. In the **Actions** pane, click either **Allow Command** or **Deny Command**. Then type the command in the **Command** box, and click **OK**.

   Warning
   The ability to add a command-based filter is an advanced feature. If you use this feature incorrectly, you could deny access to all FTP clients on your server.

Step 9: Configure FTP Logging

You can use the **FTP Logging** feature to configure logging features at the server or site level, and to configure logging settings.

To configure FTP logging

1. Open IIS Manager.
2. In the **Connections** pane, select either the server level or the site level.
3. In **Feature View**, double click the **FTP Logging** icon.
4. In the **One log file per** menu, select either **Site** or **Server**.
5. Under **Log File**, click **Select W3C Fields**, and then select the information you want go log.
6. Under **Directory**, either type the path to the base folder where you want the FTP log files stored, or click **Browse** to browse to the base folder.
7. Under **Encoding**, select either **UTF8** (single-byte and multi-byte characters) or **ANSI** (single-byte characters only).
8. Under **Log File Rollover**, select how you want FTP to create new log files from the following list:
   a. **Schedule**: select **Hourly**, **Daily**, **Weekly**, or **Monthly** to create new log files on a fixed time interval.
   b. **Maximum file size (in bytes)**: enter a positive integer to create new log files when the file size exceeds that number of bytes.
   c. **Do not create new log files**
9. Select the **Use local time for file naming and rollover** check box when you want log file naming and rollover to be based on the local time zone instead of Coordinated Universal Time (UTC).
10. In the **Actions** pane, click **Apply**.

Step 10: Configure FTP Messages

Use the **FTP Messages** feature to modify the settings for messages sent when a user connects to your FTP site.

To configure FTP messages

1. In the **Connections** pane, select either the server level or the site level.
2. In **Features View**, double-click **FTP Messages**.
3. On the **FTP Messages** page, under **Message Behavior**, select how you want your FTP messages to behave. You can select any of the following options:
   a. **Suppress default banner**: Specifies whether to display the default identification banner for the FTP server.
   b. **Support user variables in messages**: Specifies whether to display a specific set of user variables in FTP messages. The following user variables are supported:
      - %BytesReceived% - The number of bytes sent from the server to the client for the current session.
      - %BytesSent% - The number of bytes sent from the client to the server for the current session.
      - %SessionID% - The unique identifier for the current session.
      - %SiteName% - The name of the FTP site that is hosting the current session.
      - %UserName% - The account name of the currently logged-on user.
   c. **Show detailed messages for local requests**: Specifies whether to display detailed error messages when the FTP client is connecting to the FTP server on the server itself (local host).
4. Under Message Text, type messages in the following boxes:
   a. **Banner**: Specifies the message the FTP server displays when FTP clients first connect to the FTP server.
   b. **Welcome**: Specifies the message the FTP server displays when FTP clients have logged in to the FTP server.
   c. **Exit**: Specifies the message the FTP server displays when FTP clients log off the FTP server.
   d. **Maximum Connections**: Specifies the message the FTP server displays when clients try to connect and cannot because the FTP service has reached the maximum number of client connections allowed.
5. In the **Actions** pane, click **Apply**.

Build a PHP Website on IIS

This document contains an overview of the **Build a PHP website on IIS** scenario. It also contains links to additional information and community resources related to the scenario.

Did you mean…

- Build a Static Website on IIS
- Build a Classic ASP Website on IIS
- Build an ASP.NET Website on IIS
- Build a PHP Website on IIS
- Build an FTP Site on IIS
- Build a Web Farm with IIS Servers

Scenario Description

This scenario shows how to plan and configure a PHP website on an IIS 8 webserver. It is divided into two phases: a plan and design phase, and an install and configure phase. In the plan and design phase, you are provided the information needed to make informed decisions about web server installation, PHP settings, and basic application security. In the install and configure phase, you are guided through the procedures required to install IIS, add a PHP application, and configure IIS and PHP.

This scenario does not cover how to write a PHP application.

In This Scenario

- Plan a PHP Website on IIS
  - Step 1: Plan IIS Web Server and PHP Installation
  - Step 2: Plan PHP Settings
  - Step 3: Plan PHP Application Security
- Configure a PHP Website on IIS
  - Step 1: Install IIS and PHP
  - Step 2: Configure PHP Settings
  - Step 3: Configure PHP Application Security

Practical Applications

Whether you are an IT professional, a web developer, or you just want to set up your own webserver, this scenario can help you install IIS and configure it to serve your PHP web application.

Software Requirements

To get the most from this scenario, you must have access to a computer running one of the following operating systems:

- Windows Server® 2012
- Windows® 8

Plan a PHP Website on IIS

To develop a plan for installing an IIS web server and configuring it for PHP web applications, follow the steps listed.

- Step 1: Plan IIS Web Server and PHP Installation
- Step 2: Plan PHP Settings
- Step 3: Plan PHP Application Security

After you have reviewed these planning steps, see Configure a PHP Website on IIS. For more information, see Build a PHP Website on IIS.

Step 1: Plan IIS Web Server and PHP Installation

The first step in planning to build a PHP website on IIS 8 is to determine how to install IIS along with the CGI module, where to download and install the appropriate PHP version, and how to add your application files to IIS.

The following list shows the tasks required to complete this step:

1.1. Plan to Install IIS

1.2. Plan to Download and Install PHP

1.3. Plan to Add a PHP Application

When you are done with these tasks, record your design decisions before going on to Step 2: Plan PHP Settings.

1.1. Plan to Install IIS

To support PHP applications on an IIS web server, install the default configuration of IIS and the CGI module. The CGI module contains both CGI (Common Gateway Interface protocol) and FastCGI. FastCGI is a high-performance extension to CGI and is recommended for PHP applications. Once your machine has this IIS configuration installed, you can download and install PHP.

Important

To install IIS 8 on either Windows Server® 2012 or Windows® 8, you must sign on as a member of the Administrators group.

1.2. Plan to Download and Install PHP

The simplest way to install PHP is to use Web Platform Installer (Web PI). Web PI installs the latest version of PHP along with any dependencies that version requires. To learn more about the Web PI, see Learn More and Install the Web PI.

To add PHP support manually to your IIS web server, download and install the PHP runtime version that you require. You can download Windows versions of PHP from the PHP for Windows site.

There are two builds for each PHP version: one is thread-safe, and the other is non-thread-safe. The thread-safe version is designed for environments where the web server keeps the PHP engine in memory, running multiple treads of execution simultaneously. The architecture of IIS and the FastCGI extension provide an isolation model that keeps requests separate, removing the need for a thread-safe version of PHP. The non-thread-safe version of PHP gives better performance on IIS with FastCGI install than does the tread-safe version.

PHP offers several extensions that extend its base functionality. One extension is important for PHP web applications that run on IIS—the Windows Cache Extension for PHP (WinCache).

WinCache is a PHP accelerator that is used to increase the speed of PHP applications that run on Windows and Windows Server. Once the WinCache is enabled and loaded by the PHP engine, PHP applications can take advantage of the functionality without any code modifications.

You can download WinCache extension from the PHP for Windows site.

Warning
The current version of WinCache (php_winchache-svn20110402-5.2-nts-vc6-x86.zip) does not work with PHP 5.4.0. Therefore, we recommend that you install the non-thread-safe version of PHP 5.3.6 (or earlier).

1.3. Plan to Add a PHP Application

An application is a grouping of content at the root level of a website or a grouping of content in a separate folder under the website root directory. When you add an application in IIS 8, you designate a directory as the *application root*, or starting point, for the application. Then specify properties specific to that particular application, such as the application pool that the application runs in.

To configure your PHP application on an IIS website, provide the following information:

- **Alias**: The alias is used as part of the application root URL and should be short and descriptive. For example, the alias *marketing* added to the default website on the local host computer, would produce the following URL: `//localhost/marketing`.
- **Application pool**: An application pool enables an application or a group of applications to run in isolation from one or more applications in another application pool.
- **Physical path**: The local path to the application files on the server.

- Step 2: Plan PHP Settings
- Step 3: Plan PHP Application Security
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 2: Plan PHP Settings

In this phase of building your PHP website, plan to set up the WinCache PHP extension, determine what configuration settings you require for PHP, and what PHP extensions your application requires.

The following list shows the tasks required to complete this step:

2.1. Plan WinCache Configuration

2.2. Plan Other PHP Settings

2.3 Plan PHP Extensions

When you are done with these tasks, record your design decisions before going on to Step 3: Plan PHP Application Security.

2.1. Plan WinCache Configuration

WinCache is a PHP extension that accelerates PHP applications, which run on Windows and Windows Server. For the most installations, the WinCache extension must be added to the php.ini file and no other configuration is required. However, if you want more control, WinCache offers many configuration settings. You can see a full list of setting in the WinCache Runtime Configuration page.

2.2. Plan Other PHP Settings

Configuration and environmental settings for PHP are contained within the Php.ini, which is located in the PHP folder that you create during installation, for example C:\PHP. The following sections contain a number of settings for the Php.ini file that help PHP work better with Windows.

Required Settings

extension_dir = <PATH TO EXTENSIONS>

The extension_dir points to the directory where the PHP extensions are stored. The path can be fully qualified (for example, C:\PHP\ext) or relative (for example, .\ext). Extensions that are specified lower in the Php.ini file are located in the extension_dir. If the extensions specified are not in the extension_dir, then PHP displays a warning message at the start of script execution, and the application may show errors because of the missing functionality.

extension = xxxxxx.dll

For each extension enabled, a corresponding extension= directive that tells PHP which extensions in the extension_dir to load at startup time is necessary.

log_errors = On

PHP errors can also go through the PHP error logging facility. This can be used to send errors to a file or to a service (for example, syslog) and works with the error_log directive described below. When running under IIS, log_errors must be enabled with a valid error_log. Otherwise, FastCGI considers any startup messages (that may be benign) as an error condition, which generates an HTTP 500 return error code to the browser.

error_log = <path_to_error_log_file>

The error_log must specify the fully qualified, or relative, path to the file where the PHP error log is stored. This file must be writable for the IIS service. The most common places for this file are in various temporary directories (for example, C:\inetpub\temp\php-errors.log). That puts the log in a place that IIS can use and keeps the log close to where PHP applications are running.

cgi.force_redirect = 0

This directive is required for running under IIS. It is a directory security facility that is required by many other web servers. However, enabling it under IIS causes the PHP engine to fail on Windows.

cgi.fix_pathinfo = 1

This setting lets PHP access real path information per the CGI specification. The IIS FastCGI implementation needs this extension set.

fastcgi.impersonate = 1

FastCGI under IIS supports the ability to impersonate security tokens of the calling client. This setting allows IIS to define the security context that the request runs under.

fastcgi.logging = 0

FastCGI logging should be disabled when you use PHP with IIS. If it is left enabled, then any messages of any class are treated by FastCGI as error conditions, which causes IIS to generate an HTTP 500 exception.

Optional Settings

max_execution_time = ##

This directive sets the maximum amount of time that can be taken executing any given script. The default is 30 seconds. Some applications need more time to process batch operations (for example, Gallery2 loading multiple images from a remote location). However, setting the execution time higher than 300 seconds is not advised because there are often other parts of the connection that cannot support such a long execution time.

memory_limit = ###M

The amount of memory available for the PHP process (in MB). The default is 128 MB,

which is sufficient for most PHP applications.

display_errors = Off

This directive determines whether to include any error messages in the stream that it returns to the web server. If turned on, PHP sends the classes of errors that are defined with the error_reporting directive back to IIS as part of the error stream. Many of the open-source applications bypass error reporting by executing commands prefaced with @. This setting allows the applications to control error handling.

Mail functions

PHP is configured by default to send outbound mail through an SMTP server that is located on the same system as the web server. Most Windows installations usually have the web and mail servers on separate systems.

2.3 Plan PHP Extensions

It is important to determine which extensions are required by the applications you intend to run, and then to limit the installed extensions to those extensions only. For example, a typical open-source PHP application might require the following types of extensions:

- **Database Extensions**—Open-source applications that use MySQL for a database engine use either the php_mysql or the php_mysqli extension. For new development work, either of these extensions work well. Consider using the PDO versions of the MySQL driver. PDO is a PHP extension that provides a data-access abstraction layer that can be used with various databases. Microsoft provides PHP drivers for SQL server that you can download. To learn more about PHP drivers for SQL Server, see Microsoft Drivers for PHP for SQL Server.
- **Image Handling Extensions**—Open-source applications that enable work with images use the GD2 extension – php_gd2, which has several application programming interfaces (APIs) for basic image manipulation. Some applications use the ImageMagick application and libraries. There is also a php_exif library for working with the extended information that modern digital cameras store within the images.
- **Internationalization and Localization Extensions**—The two most commonly used extensions for i18n and l10n are php_mbstring (Multi-Byte String) and php_gettext (Native Language Support). Many of the open-source applications use one or both of these extensions.
- **Web Services Extensions**—Choose the web services extensions based on the services desired. For PHP, the SOAP extension is widely used. The XML-RPC extension is often used with SOAP and other services.

To view the entire list of PHP extensions available for applications that run on Windows platforms, see the complete list of Windows extensions for PHP.

- Step 2: Configure PHP Settings
- Step 1: Plan IIS Web Server and PHP Installation
- Step 3: Plan PHP Application Security
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 3: Plan PHP Application Security

In this phase of Building a PHP website on IIS, consider what PHP configuration settings, web server settings, and PHP application settings you need to strengthen security.

3.1. PHP Configuration Settings for Security

3.2. Web Server and PHP Application Security

When you are done with these tasks, record your design decisions before going on to Step 1: Install IIS and PHP.

3.1. PHP Configuration Settings for Security

The dynamic capabilities of PHP also make it a potential security risk because data is actively fetched, received, and processed from anywhere on the Internet. Attackers may attempt to send in malicious data and scripts and trick your server into fetching malicious scripts and running them. Attackers may also attempt to read and write files on your server to take control of the web site and use it for their own purposes.

You can configure PHP settings to tighten the security of a PHP installation and help protect the website from malicious attacks. The Php.ini file specifies the configuration settings PHP uses when it is running on your website. The Php.ini file determines what PHP scripts are allowed to do and prohibited from doing.

This section describes the configuration settings that help to protect your PHP applications.

Disable File Handling for Remote URLs

```
allow_url_fopen = Off
 allow_url_include = Off
```

This setting is very important because it prevents URLs from being used in statements such as include(). Setting **allow_url_fopen** to “Off” means that only files that reside within your website can be included. You can’t include a file from a different server, but neither can other people through Remote File Inclusion (RFI) attacks. In an RFI attack, someone embeds a URL in an HTTP request hoping that your script is tricked into running theirs. A command such as `include("http://website.com/page.php")`, for example, is not allowed to execute.

Include a file from your own site by specifying its path and filename. For example, if you have a URL **include** line, convert it to: `include($_SERVER['DOCUMENT_ROOT'] . '/page.php');`

The code segment `$_SERVER['DOCUMENT_ROOT']` is a superglobal variable set to the root folder of your site. (Note that there is no trailing "/"; you must provide a leading "/" in '/page.php'.)

If you want to include static content from another one of your websites, such as `include('http://myothersite.com/includes/footer.php')`, make a copy of that content in the current site and then include it locally.

Disable Register_Globals

```
register_globals = Off
```

This setting makes it difficult for an attacker to inject code into your script. For example, in `URL http://site.com/index.php?variable=value`, the variable passes into your script with its value set to **value** when **register_globals** is **On**. When **register_globals** is **Off**, however, variables do not automatically pass into your script's variable list.

Restrict File System Read/Write

```
open_basedir = "c:\inetpub\"
```

This setting restricts PHP scripts from accessing files outside the specified base directory.

Disable Safe Mode

```
safe_mode = Off
 safe_mode_gid = Off
```

This setting restricts the permissions with which PHP scripts run. Some third-party scripts do not run properly when safe_mode is set to "On." Note that beginning with PHP 6 safe_mode does not exist.

Limit Script Execution Time

```
max_execution_time = 30
 max_input_time = 60
```

These settings control the number of seconds a script is allowed to run and parse user input. These settings help prevent poorly written scripts from typing up the server.

Limit Memory Usage and File Size

```
memory_limit = 16M
 upload_max_filesize = 2M
 post_max_size = 8M
 max_input_nesting_levels = 64
```

These settings help manage memory and input/output efficiently. In addition, they prevent poorly written scripts from hogging memory and handling huge files.

Configure Error Logging

```
display_errors = Off
display_startup_errors = Off log_errors = On
error_log = "C:\path\of\your\choice"
```

These settings specify that all errors and warnings get logged to your error log text file and specify that none of the errors or warnings get displayed on any web page that is sent out from your server. Errors should not be displayed publicly because they can help someone figure out how to attack your server. Always check your error log when you are testing new code.

Enable FastCGI Impersonation

```
fastcgi.impersonate = 1
```

This setting enables IIS to impersonate the security tokens of calling client and define the security context that is used to run the request.

Disable FastCGI Logging

```
fastcgi.logging = 0
```

The FastCGI module will fail the request when PHP sends any data on **stderr** by using FastCGI protocol. Disabling FastCGI logging will prevent PHP from sending error information over **stderr**, and generating 500 response codes for the client.

Hide PHP Presence

```
expose_php = Off
```

With this setting, the headers that accompany outgoing pages do not reveal that PHP is running or its version.

3.2. Web Server and PHP Application Security

Isolate Web Applications

One of the most effective ways to improve security for your web application is to isolate it from other applications on your web server. An application pool has its own worker process, which processes requests and runs application code. The worker process has a security identifier (SID). And each application pool has a unique application-pool identity. By default, when you create a web application, a new application pool is also created with the same name as the application. If you keep web applications in separate application pools, you can isolate them from one another.

Web application isolation entails the following:

- Site isolation: Separate different applications into different sites with different application pools.

- Least privilege: Run your worker process as a low privileged identity (virtual application pool identity) that is unique per site.
- Temp isolation: Set up a separate PHP temp folder per site and only give access to appropriate process identity.
- Content isolation: Make sure to set an ACL (access control list) on each site root to allow only access to the appropriate process identity.

Tip
It is a good idea to host your website and web application content on a drive other than your system drive (C:).

Enable Per-site PHP Configuration

The FastCGI handler makes it possible to use a different Php.ini file for every application mapping. You can customize your PHP configuration around the specific requirements of your users or your PHP applications, letting you tighten configuration.

Use Request Filtering

The request filtering module inspects known malicious patterns in the requests and prevents such requests from being serviced if the module determines that the requests may be harmful. For example, this module lets you filter requests that are double escaped, filter requests that use certain HTTP verbs, or block requests to specific folders. You can enforce tighter security policies on your web servers with the request filtering module. For more information about request filtering, see Configure Request Filtering in IIS.

- Plan a PHP Website on IIS
- Step 1: Install IIS and PHP
- Step 1: Plan IIS Web Server and PHP Installation
- Step 2: Plan PHP Settings
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Configure a PHP Website on IIS

To install an IIS web server and configure it for PHP web applications, follow the steps listed.

- Step 1: Install IIS and PHP
- Step 2: Configure PHP Settings
- Step 3: Configure PHP Application Security

For planning information to review before deployment, see Plan a PHP Website on IIS. For more information, see Build a PHP Website on IIS.

Step 1: Install IIS and PHP

In this step of building a PHP website, you install IIS and FastCGI, download and install PHP and the WinCache extension, and upload your PHP application.

The following list shows the tasks required to complete this step:

1.1. Install IIS

1.2 Install PHP by using Web PI

1.3. Download and Install PHP Manually

1.4. Add Your PHP Application

When you are done, make sure that IIS and the PHP are installed, and your PHP application has been added to your website. Then go on to Step 2: Configure PHP Settings.

1.1. Install IIS

You can use the Web Platform Installer (Web PI) to install IIS, and applications that run on IIS. Web PI installs the latest versions of available Web Platform offerings with just a few simple clicks. Using Web PI, you can download and install any new tools or updates, including PHP. To learn more about the Web PI, see Learn more and install the Web PI.

If you do not use Web PI to install IIS, you can install IIS manually. To install IIS manually, use the following steps:

To install IIS on Windows Server 2012

1. On the **Start** page, click the **Server Manager** tile, and then click **OK**.
2. In **Server Manager**, select **Dashboard**, and click **Add roles and features**.
3. In the **Add Roles and Features Wizard**, on the **Before You Begin** page, click **Next**.
4. On the **Select Installation Type** page, select **Role-based or Feature-based Installation** and click **Next**
5. On the **Select Destination Server** page, select **Select a server from the server pool**, select your server, and click **Next**.
6. On the **Select Server Roles** page, select **Web Server (IIS)**, and then click **Next**.
7. On the **Select Features** page, note the preselected features that are installed by default, and then select **CGI**. This selection also installs FastCGI, which is recommended for PHP

applications.

8. Click **Next**.
9. On the **Web Server Role (IIS)** page, click **Next**.
10. On the **Select Role Services** page, note the preselected role services that are installed by default, and then click **Next**.

    Note
    You only have to install the IIS 8 default role services for a static-content web server.

11. On the **Confirm Installation Selections** page, confirm your selections, and then click **Install**.
12. On the **Installation Progress** page, confirm that your installation of the Web Server (IIS) role and required role services completed successfully, and then click **Close**.
13. To verify that IIS installed successfully, type the following into a web browser:

    http://localhost

    You should see the default IIS Welcome page.

To install IIS on Windows 8

1. On the **Start** page, type **Control Panel**, and then click the **Control Panel** icon in the search results.
2. In **Control Panel**, click **Programs**, and then click **Turn Windows features on or off**.
3. In the **Windows Features** dialog box, click **Internet Information Services**, note the preselected features that are installed by default, and then select **CGI**. This selection also installs FastCGI, which is recommended for PHP applications.
4. Click **OK**.
5. To verify that IIS installed successfully, type the following into a web browser:

    http://localhost

    You see the default IIS Welcome page.

1.2 Install PHP by using Web PI

The preferred method to install PHP on a Windows or Windows Server computer is to use Web Platform Installer (Web PI).

To install PHP manually

1. Open a browser to the following website: Microsoft Web Platform Installer 3.0.
2. Click **Download It Now**, and then click **Run**.
3. At the top of the **Web Platform Installer** window, click **Products**.
4. Click **Frameworks**, and then select the current version of PHP. (At this writing, the current version is PHP 5.3.13.)

5. Click **Install**.

   The **Web Platform Installation** page displays the version of PHP and its dependencies that will be installed.
6. Click **I Accept**.

   Web PI installs the PHP packages.
7. Click **Finish**.

1.3. Download and Install PHP Manually

If you decide to download PHP and install it manually, the procedures in this section guide you the following tasks:

- Download PHP and the WinCache extension.
- Install PHP and WinCache.
- Add the PHP installation folder to the Path environment variable.
- Set up a handler mapping for PHP.
- Add default document entries for PHP.
- Test your PHP installation.

To keep this procedure simple, install the WinCache extension but do not configure it. You will configure and test WinCache in Step 2: Configure PHP Settings.

To download and install PHP and WinCache

1. Open your browser to Windows for PHP Download Page and download the PHP 5.3 non-thread-safe zip package.

   Caution
   The PHP 5.4 version does not work with the WinCache extension version 1.1. Use PHP 5.3 until this problem is resolved.
2. Download the WinCache extension (Php_wincache-svn20110402-5.2-nts-vc6-x86.zip) from the List of Windows Extensions for PHP.
3. Extract all files in the PHP .zip package to a folder of your choice, for example C:\PHP\.
4. Extract the WinCache .zip package to the PHP extensions folder (\ext), for example C:\PHP\ext.

   The WinCache .zip package contains one file (Php_wincache.dll).
5. Open **Control Panel**, click **System and Security**, click **System**, and then click **Advanced system settings**.
6. In the **System Properties** window, select the **Advanced** tab, and then click **Environment Variables**.
7. Under **System variables**, select **Path**, and then click **Edit**.
8. Add the path to your PHP installation folder to the end of the **Variable value**, for example **;C:\PHP**. Click **OK**.

9. Open IIS Manager, select the hostname of your computer in the **Connections** panel, and then double-click **Handler Mappings**.
10. In the **Action** panel, click **Add Module Mapping**.
11. In **Request path**, type ***.php**.
12. From the **Module** menu, select FastCgiModule.
13. In the **Executable** box, type the full path to Php-cgi.exe, for example **C:\PHP\Php-cgi.exe**.
14. In **Name**, type a name for the module mapping, for example **FastCGI**.
15. Click **OK**.
16. Select the hostname of your computer in the **Connections** panel, and double-click **Default Document**.
17. In the **Action** panel, click **Add**. Type **Index.php** in the **Name** box, and then click **OK**.
18. Click **Add** again. Type **Default.php** in the **Name** box, and then click **OK**.

To test your PHP installation

1. Open a text editor, for example Notepad, as Administrator.
2. In a new file, type the following text: `<?php phpinfo(); ?>`
3. Save the file as **C:\inetpub\wwwroot\Phpinfo.php**.
4. Open a browser and enter the following URL: **http://localhost/phpinfo.php**

   A nicely formatted webpage is displayed showing the current PHP settings.

1.4. Add Your PHP Application

Once you have IIS and PHP installed, you can add a PHP application to your web server. This section describes how to set up your PHP application on an IIS web server with PHP installed. It does not explain how to develop a PHP application.

To add a PHP web application

1. Open IIS Manager.
   - For Windows Server 2012, on the **Start** page click the **Server Manager** tile, and then click **OK**. On the **Server Manager Dashboard**, click the **Tools** menu, and then click **Internet Information Services (IIS) Manager**.
   - For Windows 8, on the **Start** page type **Control Panel**, and then click the **Control Panel** icon in the search results. On the **Control Panel** screen, click **System and Security**, click **Administrative Tools**, and then **click Internet Information Services (IIS) Manager**.
2. In the **Connections** pane, right-click the **Sites** node in the tree, and then click **Add Website**.
3. In the **Add Website** dialog box, type a friendly name for your website in the **Site name** box.

4. If you want to select a different application pool than the one listed in the **Application Pool** box, click **Select**. In the **Select Application Pool** dialog box, select an application pool from the **Application Pool** list and then click **OK**.
5. In the **Physical path** box, type the physical path of the website's folder, or click the browse button (**...**) to navigate the file system to find the folder.
6. If the physical path that you entered in step 5 is to a remote share, click **Connect as** to specify credentials that have permission to access the path. If you do not use specific credentials, select the **Application user (pass-through authentication)** option in the **Connect As** dialog box.
7. Select the protocol for the website from the **Type** list.
8. The default value in the **IP address** box is **All Unassigned**. If you must specify a static IP address for the website, type the IP address in the **IP address** box.
9. Type a port number in the **Port** text box.
10. Optionally, type a host header name for the website in the **Host Header** box.
11. If you do not have to make any changes to the site, and you want the website to be immediately available, select the **Start Web site immediately** check box.
12. Click **OK**.

- Step 2: Configure PHP Settings
- Step 3: Configure PHP Application Security
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 2: Configure PHP Settings

In this step of building a PHP website on IIS, you configure the WinCache PHP extension, configure PHP settings, and download and configure any other PHP extensions that your application requires.

2.1. Configure WinCache

2.2. Configure Other PHP Settings

2.3 Configure PHP Extensions

When you complete these tasks, continue to Step 3: Configure PHP Application Security.

2.1. Configure WinCache

Before you perform this procedure, you should download in install PHP and WinCache as described in 1.2 Download and Install PHP.. For more information about WinCache, see 2.1. Plan WinCache Configuration.

To configure the WinCache PHP extension

1. In Windows Explorer, open your PHP installation folder, for example **C:\PHP**.
2. Choose either the **php.ini - development** or **php.ini - production** file, and rename it **php.ini**.
3. In a text editor, open the php.ini file and added the following line at the end of the file:
   `extension = php_wincache.dll.`
4. Save and close the php.ini file.
5. Recycle the IIS Application Pools for PHP to pick up the configuration changes.

To view WinCache configuration and other PHP settings

1. Open a text editor.
2. In a new file, type the following text: `<?php phpinfo(); ?>`
3. Save the file as **c:\inetpub\wwwroot\phpinfo.php**.
4. Open a browser and enter the following URL: **http://localhost/phpinfo.php**

   A nicely formatted web page is displayed showing the current PHP settings. The WinCache settings appear in a section called **wincache**.

   Warning
   Delete the phpinfo.php file when it's no longer needed.

2.2. Configure Other PHP Settings

The following procedure explains how to configure PHP settings in the php.ini file. For more information about PHP settings, see 2.2. Plan other PHP settings.

To configure a PHP setting

1. In Windows Explorer, open your PHP installation folder, for example **C:\PHP**.
2. In a text editor, open the php.ini file.
3. Search the file for the setting you want to change.

   If the setting is commented out (line begins with a semicolon [;]), delete the semicolon and set the value. If you can't find the setting, add the line to the end of the file.
4. Save and close the php.ini file.
5. Recycle the IIS Application Pools for PHP to pick up the configuration changes.

2.3 Configure PHP Extensions

The following procedure shows how to download and install a PHP extension. For information about PHP extensions, see 2.3 Plan PHP Extensions.

To configure a PHP extension

1. Download the PHP extension you want from the list of Windows extensions for PHP.
2. Extract the extension zip package to the PHP extensions folder (\ext), for example C:\PHP\ext.
3. In Windows Explorer, open your PHP installation folder, for example C:\PHP.
4. In a text editor, open the php.ini file.
5. Search the file for the extension you want to configure.

   If the extension is commented out (line begins with a semicolon [;]), delete the semicolon. If you can't find the extension, add it to the end of the file. A line that adds an extension is in the form: `extension = extension_name.dll`. For example: `extension = php_soap.dll`.
6. Save and close the php.ini file.
7. Recycle the IIS Application Pools for PHP to pick up the configuration changes.

- Step 3: Configure PHP Application Security
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 3: Configure PHP Application Security

In this last step in building a PHP website on IIS, you configure PHP settings, web server settings, and PHP application settings that improve your website security.

3.1. Configure PHP Settings for Security

3.2. Configure Web Server and PHP Application Security

3.1. Configure PHP Settings for Security

The following procedure shows you how to configure PHP settings in the php.ini file. For information about security-related PHP settings, see 3.1. PHP Configuration Settings for Security.

To configure a PHP setting for security

1. In Windows Explorer, open your PHP installation folder, for example **C:\PHP**.
2. In a text editor, open the php.ini file.
3. Search the file for the setting you want to change.

   If the setting is commented out (line begins with a semicolon [;]), delete the semicolon and set the value. If you can't find the setting, add the line to the end of the file.
4. Save and close the php.ini file.
5. Recycle the IIS Application Pools for PHP to pick up the configuration changes.

3.2. Configure Web Server and PHP Application Security

This section shows how to configure several web server and application settings for IIS. These settings include isolating web applications, enabling per-site PHP configurations, and using request filtering. For more information about web server and PHP application security settings, see 3.2. Web Server and PHP Application Security.

Isolate Web Applications

Implement the following recommendations to isolate websites and web applications on your server.

- Use one application pool per website or web application.
- Limit access to site folders and files to the application pool identity.
- Set up a separate PHP temp folder per site and only give access to the application pool identity.
- Make sure to set an ACL (access control list) on each site root to allow only access to the application pool identity.

If you have more than one application per application pool, consider creating enough application pools and moving some of the applications to the new pools.

To create an application pool

1. Open IIS Manager.
2. In the **Connections** pane, click **Application Pools**.
3. In the **Actions** pane, click **Add Application Pool**.
4. In the **Name** box, type a unique name for the application pool.
5. Under **.NET Framework version**, select **No Managed Code**.
6. Select the **Managed pipeline mode**. The **Integrated** mode is recommended.
7. Click **OK**.

To move an application to another application pool

1. Open IIS Manager.
2. In the **Connections** page, select the website or web application you want to move.
3. In the **Actions** pane, click **Basic Settings**.
4. On the **Edit Site** dialog, click **Select** to open the **Select Application Pool** dialog, and then select the application pool from the **Application pool** menu.
5. Click **OK** to close the **Select Application Pool** dialog, and click **OK** to close the **Edit Site** menu.

To add an application pool identity to a folder or file ACL

1. Open Windows Explorer and navigate to the folder or file.
2. Right click the folder or file, and then click **Properties**.
3. Select the **Security** tab, and then click **Edit**.
4. Click **Add**, click **Locations**, and select your server as the location to search.
5. In the **Enter the object names to select** box, type **IIS APPPOOL\applicationPoolName**, where *applicationPoolName* is the application pool identity.
6. Click **OK**, click **OK**, and click **OK** again to close the dialogs.

Enable Per-site PHP Configuration

When you have multiple PHP applications on an IIS web server, you can improve security by configuring a PHP process pool and a php.ini file for each application. This section explains how to configure process pools and multiple pnp.ini files by using an **applicationHost.config** file.

Per-site PHP Process Pools

When each website has its own application pool, which is a recommended practice on IIS, it is possible to associate a dedicated FastCGI process pool with each website. This association is done in the **fastCgi** section of the **applicationHost.config** file. A FastCGI process pool is uniquely identified by the combination of **fullPath** and **arguments** attributes of the **application** element. To create several FastCGI process pools for the same process executable, such as php-cgi.exe, use the **arguments** attribute to distinguish the process pool definitions. With php-cgi.exe processes, use the command line switch "-d" to define an INI entry for a PHP process. And use this switch to set a PHP setting that makes the arguments string unique.

For example, if there are two Web sites "website1" and "website2" that must have their own set of PHP settings, define the FastCGI process pools as follows:

```
<fastCgi>
  <application fullPath="C:\PHP\php-cgi.exe"
    arguments="-d open_basedir=C:\Websites\Website1" />
  <application fullPath="C:\PHP\php-cgi.exe"
    arguments="-d open_basedir=C:\Websites\Website2" />
```

```
</fastCgi>
```

In this example the PHP setting `open_basedir` is used to distinguish between the process pool definitions. The setting also enforces that the PHP executable for each process pool can perform file operations only within the root folder of the corresponding website.

Therefore, the PHP handler mapping for website1 is as follows:

```
<system.webServer>
  <handlers accessPolicy="Read, Script">
    <add name="PHP via FastCGI"
      path="*.php" verb="*"
      modules="FastCgiModule"
      scriptProcessor="C:\PHP\php-cgi.exe|-d open_basedir=C:\Websites\Website1"
      resourceType="Unspecified"
      requireAccess="Script" />
  </handlers>
</system.webServer>
```

And the handler mapping for website2 is as follows:

```
<system.webServer>
  <handlers accessPolicy="Read, Script">
    <add name="PHP via FastCGI"
      path="*.php" verb="*"
      modules="FastCgiModule"
      scriptProcessor="C:\PHP\php-cgi.exe|-d open_basedir=C:\Websites\Website2"
      resourceType="Unspecified" requireAccess="Script" />
  </handlers>
</system.webServer>
```

Specifying Php.ini Location

When the PHP process starts, it determines the location of the configuration php.ini file by using various settings. The PHP documentation provides a detailed description of the PHP startup process. One of the places where the PHP process searches for the php.ini location is the PHPRC environment variable. If the PHP process finds a php.ini file in the path that is specified in this environment variable, it will use it. Otherwise, the PHP process will revert to using the default location of the php.ini file. This environment variable can be used to allow hosting customers to use their own versions of php.ini files.

For example, if there are two websites, "website1" and "website2," that are located at the following file paths: `C:\WebSites\website1` and `C:\WebSites\website2`, you can configure the php-cgi.exe process pools in the **fastCgi** section of the **applicationHost.config** file as follows:

```
<fastCgi>
  <application fullPath="C:\PHP\php-cgi.exe" arguments="-d
open_basedir=C:\Websites\Website1">
    <environmentVariables>
      <environmentVariable name="PHPRC" value="C:\WebSites\website1" />
    </environmentVariables>
  </application>
  <application fullPath="C:\PHP\php-cgi.exe" arguments="-d
open_basedir=C:\WebSites\Website2">
    <environmentVariables>
      <environmentVariable name="PHPRC" value="C:\WebSites\website2" />
    </environmentVariables>
  </application>
</fastCgi>
```

This way website1 can have its own version of the php.ini file that is located in the `C:\WebSites\website1`, while website2 can have its own version of the php.ini file that is located in `C:\WebSites\website2`. This configuration also ensures that if a php.ini file cannot be found in the location that is specified by the PHPRC environment variable, then PHP will use the default php.ini file that is located in the same folder where the php-cgi.exe is located.

Use Request Filtering

For information about how to configure request filtering, see Configure Request Filtering in IIS.

Build a Web Farm with IIS Servers

This document contains an overview of the **Build a web farm with IIS servers** scenario. It also contains links to additional information and community resources related to the scenario.

Did you mean…

- Build a Static Website on IIS
- Build a Classic ASP Website on IIS
- Build an ASP.NET Website on IIS
- Build a PHP Website on IIS
- Build an FTP Site on IIS
- Web Farm Framework

Scenario Description

This scenario shows how to plan and configure a web farm with servers that run the Windows Server® 2012 operating system.

The scenario is divided into two phases: a plan and design phase, and an install and configure phase. In the plan and design phase, you learn what the concepts needed to configure a web farm that keeps its server configuration and content synchronized, balances server load, and stores SSL certificate centrally. In the install and configure phase, you are guided through the procedures required to install IIS web server, configure a back-end content server, configure load balancing, and configure a central certificate store for SLL.

In This Scenario

- Plan a Web Farm with IIS Servers
  - Step 1: Plan IIS Web Farm Infrastructure
  - Step 2: Plan IIS Web Farm Configuration
  - Step 3: Plan IIS Web Farm Load Balancing
  - Step 4: Plan SSL Central Certificate Store
  - Step 5: Plan Application Deployment
- Configure a Web Farm with IIS Servers
  - Step 1: Install IIS Web Farm Infrastructure
  - Step 2: Configure IIS Web Farm Servers
  - Step 3: Configure IIS Web Farm Load Balancing
  - Step 4: Configure SSL Central Certificate Store
  - Step 5: Configure Application Deployment

Practical Applications

Whether you are an IT professional, a web developer, or you just want to set up your own web farm, this scenario can help you install and configure a fully functional web farm with IIS web servers.

Software Requirements

To get the most from this scenario, you must have administrator access to at least five computers (or virtual machines) that run the Windows Server 2012 operating system.

Plan a Web Farm with IIS Servers

To develop a plan for installing and configuring an IIS web farm, follow the steps listed.

- Step 1: Plan IIS Web Farm Infrastructure
- Step 2: Plan IIS Web Farm Configuration
- Step 3: Plan IIS Web Farm Load Balancing
- Step 4: Plan SSL Central Certificate Store
- Step 5: Plan Application Deployment

For planning information you should review before deployment, see Plan a Web Farm with IIS Servers. For more information, see Build a Web Farm with IIS Servers.

Step 1: Plan IIS Web Farm Infrastructure

The first step in planning your web farm is to decide its infrastructure. What server configuration do you want? What technologies do you employ? How do you perform load balancing? Does your site need SSL security?

This topic presents the information you need to create a high-level plan for your web farm. It selects a simple web farm configuration and shows the types of servers that are required. In addition, this topic explains how Application Request Routing (ARR) provides load balancing for the web farm.

The following list shows the tasks required to complete this step:

1.1. Decide on Web Farm Infrastructure

1.2. Use ARR for Load Balancing

1.3. Start with a Functional Website

When you are done with these tasks, record your design decisions before going on to Step 2: Plan IIS Web Farm Configuration.

1.1. Decide on Web Farm Infrastructure

There are many ways to design the infrastructure of a web farm. This discussion looks briefly at two common infrastructures—local content and shared network content. It compares advantages and disadvantages of both designs, and selects one for this scenario.

Local Content Infrastructure

The local content infrastructure requires that each web server keeps the content locally. A way must be provided to push the content to all nodes of the web farm.

Advantages

- Local content provides isolation between servers. If one server goes down, other servers are not affected.
- Local content requires fewer computers, because it does not need a back-end content file server.
- You can easily take a web server off line for testing or troubleshooting.

Disadvantages

- Content must be replicated between servers. A common way to handle content replication is by using Distributed File System Replication (DFSR). However, DFSR requires access to a domain server.
- If the website writes to a disk, the data is not available to other servers until it is replicated.
- Each server must have a complete copy of all content. For large websites, the cost of content storage can be high.

Shared Network Content Infrastructure

Shared network content configures all web servers point to a central location (for example, a back-end file server) that contains the website content.

Advantages

- Shared network content is relatively simple to configure and is a good starting point for individuals who are new to web farms or to Microsoft web farm technologies.
- Content written to disk is immediately available on all servers.
- Adding additional servers to the farms is relatively easy. You simply point to the content UNC path.
- Only a few copies of the website files need to be kept. Hard disks on the web servers need contain only the operating system.

Disadvantages

- The back-end file server is a single point of failure. This problem can be minimized by mirroring the file server and providing a means of failover control.
- Network bandwidth can become a limiting factor for a busy web farm.
- File locking issues might arise as multiple servers use the same files.

The Infrastructure Chosen for This Scenario

This scenario uses the shared network content infrastructure. It describes and demonstrates shared content, shared configuration, software load balancing, centralized SSL certificates, and application deployment techniques.

This web farm infrastructure requires you to configure the following servers:

- One Application Request Routing (ARR) server for load balancing. This server requires a default installation of IIS web server. For more information about ARR, see Step 3: Plan IIS Web Farm Load Balancing.
- Two or more web servers. These servers require you to install IIS web server and the IIS modules required to support your website.
- One file server for content and configuration sharing. Set up this server with shared folders for configuration file and website content.
- One file server for the SSL central certificate store. For more information about central certificate store, see Step 4: Plan SSL Central Certificate Store.

1.2. Use ARR for Load Balancing

Microsoft Application Request Routing (ARR) is a proxy-based routing module that forwards HTTP requests to content servers based on HTTP headers, server variables, and load balance algorithms. For more information about ARR, see Step 3: Plan IIS Web Farm Load Balancing.

The easiest way to install ARR and its dependencies is with Web Platform Installer.

To configure ARR load balancing, you need the IP address for all of your servers. To find an IP address, use the Ipconfig.exe command-line tool.

1.3. Start with a Functional Website

The easiest way to configure your web farm is to start by getting your website working on one server. If you need help configuring your website, refer to one or more of the following IIS scenarios:

1. Build a Static Website on IIS
2. Build a Classic ASP Website on IIS
3. Build an ASP.NET Website on IIS
4. Build a PHP Website on IIS
5. Build an FTP Site on IIS

Note
To keep this scenario simple, it is assumed that your web farm servers only one site. However, you can set up multiple sites with little difficulty.

See Also

- Step 2: Plan IIS Web Farm Configuration
- Step 1: Install IIS Web Farm Infrastructure
- Plan a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 2: Plan IIS Web Farm Configuration

In the second phase of planning a web farm, determine what is needed to configure shared content and shared configuration. In addition, learn how to add web servers to your farm.

The following list shows the tasks required to complete this step:

2.1. Plan for Shared Content

2.2. Plan for Shared Configuration

2.3 Plan to Add Web Servers

When you are done with these tasks, record your design decisions before going on to Step 3: Plan IIS Web Farm Load Balancing.

2.1. Plan for Shared Content

Network shared content uses a back-end file server to manage website content. All web servers point to a shared folder on the file server over a UNC path. To reduce the risk of failure, the file server is often mirrored to another server with some method of failover provided. For information about failover clusters, see Failover Clustering.

To configure shared content, you first set up the shared folder on the file server. Create a custom user for each application pool and assign that user to the shared folder. You can create local users and groups as long as the same username and password is assigned to each web server.

If your web farm supports ASP.NET applications, use the Code Access Security Policy tool (Caspol.exe) to grant ASP.NET approval for the UNC path. With the Caspol tool, you can grant full trust to the UNC path on your web server. The tool resides on your server at one of the following locations:

- 64-bit systems: %windir%\Microsoft.NET\Framework64\v4.030319
- 32-bit systems: %windir%\Microsoft.NET\Framework\v4.030319

Run the tool by using either a system command prompt, a PowerShell command prompt, or a Visual Studio command prompt. For more information, see Step 2: Configure IIS Web Farm Servers.

2.2. Plan for Shared Configuration

Shared configuration is an IIS feature that helps support homogeneous web farms where all web servers share the same configuration. By using a UNC share, any changes to a master configuration file propagate across different servers without extra tools or programmatic support.

You enable shared configuration in two steps by using the IIS Manager.

1. Export the configuration files to a shared folder on the back-end file server.
2. Point IIS to the UNC path for that shared folder.

2.3 Plan to Add Web Servers

To add web servers to you farm, first use IIS Manager to set up shared configuration by pointing to the configuration UNC path. When you restart IIS Manager, the shared site or sites will be listed. If your web farm supports ASP.NET applications, run the Caspol tool on the new server.

- Step 3: Plan IIS Web Farm Load Balancing
- Step 1: Plan IIS Web Farm Infrastructure
- Step 2: Configure IIS Web Farm Servers

- Plan a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 3: Plan IIS Web Farm Load Balancing

In this phase of planning a web farm with IIS servers, you learn about load balancing. You also learn how to configure load balancing by using Application Request Routing (ARR). ARR is a proxy-based request routing and load balancing module for IIS.

The following list shows the tasks required to complete this step:

3.1. Plan Load Balancing with ARR

3.2. Survey Other Features of ARR

When you are done with these tasks, record your design decisions before going on to Step 4: Plan SSL Central Certificate Store.

3.1. Plan Load Balancing with ARR

Load balancing is a way to distribute workload across multiple web servers. The purpose is to attain optimal resource utilization, maximize request throughput, minimize response time, and avoid server overload.

Load balancers use various algorithms to accomplish this task. One of the simplest algorithms is round robin, which sends each new request to a different web server in an attempt to load all servers equally. Other algorithms send specific types of requests to specific servers in an attempt to reduce response time.

Application Request Routing (ARR) is a proxy-based routing module that uses HTTP headers, server variables, and load balance algorithms to determine how to forward requests to content servers. ARR leverages the URL Rewrite module to inspect incoming requests.

A key feature of ARR is called *host name affinity*. Host name affinity creates an affinity (close connection) between requests and a given server (or set of servers). This ensures that a given site is consuming resources only on a defined number of servers.

Prepare a list of IP addresses for all servers in your farm. You will need the list to configure ARR load balancing.

3.2. Survey Other Features of ARR

In addition to load balancing, ARR provides many features that are beyond the scope of this scenario. The following table summarizes the features that are available in ARR.

Feature	Description
Browsing cached contents with the UI	Cached contents across multiple drives, including cached directories and files, are viewable in IIS Manager.
Byte-range support	ARR segments byte-range requests into smaller pieces to help increase the cache hit/miss ratio without impacting the response time.
Cache hierarchy management	ARR lets you define and manage relationships between the cache nodes. It supports the Cache Array Routing Protocol (CARP), so that you can configure ARR as an edge cache node.
Cache proxy node in CDN/ECN environment	ARR can be used as a cache proxy in a content delivery network (CDN) or edge cache network (ECN) deployment. Because ARR is a proxy-based HTTP request-routing module with support for disk cache and CARP.
Caching compressed objects	ARR compresses and stores objects in a disk-based cache so that these objects remain uncompressed in real time for every request.
Caching while serving responses	ARR can cache large files while serving the response in real time.
Client affinity	ARR can use cookies to affinitize all requests from a client to a content server.
Disk-based caching	ARR supports cached content on user-specified primary cache drives and a secondary network-based cache drive.
Failed request tracing rules	ARR uses tracing rules to troubleshoot and diagnose failed requests.
Health monitoring	ARR provides configuration parameters to use in live traffic and specific URL tests to determine the health of content servers.
Host name affinity	Host name affinity—a feature specific to shared hosters—changes the deployment topology by providing two providers, round robin and memory, to determine which server the host

Feature	Description
	affinitizes.
HTTP-based routing decisions	Application Request Routing works with the URL Rewrite module to write routing rules that are based on HTTP headers and server variables, and to make routing decisions at the application level.
Live request support	ARR supports live content requests by consolidating requests and checking the cache-miss requests before forwarding requests to the origin server.
Load balance algorithms	ARR provides six load balance algorithms that you can use to identify which content server to use to service HTTP requests.
Management and monitoring using the UI	ARR configuration settings and runtime statistics are viewable in IIS Manager.
Multiple server groups	ARR can manage multiple groups of content servers in pilot management and A/B testing scenarios.
Overriding cache-control directives	ARR lets you manually override cache-control directives that control caching behavior, such as the ability to cache and cache duration.
Removing cached contents	ARR lets you delete cached contents by matching URL patterns.
Warming up cache nodes	ARR lets you pre-cache content, anticipating demand before the content is requested. You can pre-cache the parent cache tier only or both the parent and child cache tiers.

- Step 4: Plan SSL Central Certificate Store
- Step 2: Plan IIS Web Farm Configuration
- Step 3: Configure IIS Web Farm Load Balancing
- Plan a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 4: Plan SSL Central Certificate Store

In this phase of planning for a web farm, you add support for SSL-secured websites by configuring a central certificate store. Centralized SSL certificate support is a new feature on IIS 8.

The following list shows the tasks required to complete this step:

4.1. Introduction to Centralized Certificates

4.2 Plan a Central Certificate Store

When you are done with these tasks, record your design decisions before going on to Step 5: Plan Application Deployment.

4.1. Introduction to Centralized Certificates

On Windows Server® 2012, the **Centralized SSL Certificate Support** feature allows server administrators to store and access the certificates centrally on a file share. You can configure a centralized certificate store on you web farm to load the certificates from the file share.

Using centralized certificates simplifies management SSL bindings. SSL requires the DNS name and CN name of a certificate to match. Similar contract can be extended to the file names of the certificates. For example, *www.contoso.com* would use the certificate with a file name *www.contoso.com.pfx*. This contract enables Windows Server 2012 to have just one SSL binding, regardless of the number of secure sites that are using this feature. IIS 8 infers what certificate to use by the SNI value or hostname of the requested website, and by matching it to the file name of the certificate.

4.2 Plan a Central Certificate Store

Similar to shared configuration, the centralized certificates uses a shared folder on a dedicated back-end file server to store the certificates for the web farm. Do not put the certificate shared folder on the content file server.

The central certificate store requires certificates to use the following naming conventions:

- Certificate names must the following form: CN_name.pfx (for example, www.contoso.com.pfx).
- If the certificate is a wild character certificate, use an underscore (_) as the wild character (for example, _.contoso.com.pfx).
- If the certificate has multiple CN names, they must be named as individual files (for example, www.contoso1.com.pfx, www.contoso2.com.pfx, and so forth).

- Step 3: Plan IIS Web Farm Load Balancing

- Step 4: Configure SSL Central Certificate Store
- Plan a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 5: Plan Application Deployment

When your web farm is up and working, you will want to update your website or add new websites to your server. File Transfer Protocol (FTP) has existed since the early days of the internet for this purpose. Microsoft's Web Deployment Tool (Web Deploy) simplifies deployment of the complex web applications of today.

In this step of building a web farm, you plan the installation and configuration of FTP and Web Deploy for you web farm.

The following list shows the tasks required to complete this step:

5.1. Deploy Websites with FTP

5.2 Deploy Web Applications with Web Deploy

When you are done with these tasks, record your design decisions before going on to Step 1: Install IIS Web Farm Infrastructure.

5.1. Deploy Websites with FTP

File Transfer Protocol (FTP) simple is a protocol for transferring files between computer systems. IIS 8 includes an FTP server that is easy to configure. For the web farm in this scenario, install FTP on the load balancing computer (ARR server) and configure it to point to the back-end shared content. For more information about FTP configuration, see Build an FTP Site on IIS.

5.2 Deploy Web Applications with Web Deploy

The Web Deployment Tool (Web Deploy) enables IIS to synchronize, package, and deploy web applications, websites, or web server content and configuration. It has numerous features that let you include those components that you want to process and exclude those components that you do not. For you to be able to use Web Deploy, first install IIS on the source and destination computers.

The easiest way to install Web Deploy is by using the Web Platform Installer. You can install Web Deploy by running the Web Deploy Windows® Installer or from the command line by using Msiexec.exe. The Web Platform Installer requires fewer steps, while the other methods allow you to customize your installation. In all cases, log on as an administrator.

For more information about Web Deploy, see Web Deployment Tool Overview and Introduction to Web Deploy.

Configure a Web Farm with IIS Servers

To install and configure an IIS web farm, follow the steps listed.

- Step 1: Install IIS Web Farm Infrastructure
- Step 2: Configure IIS Web Farm Servers
- Step 3: Configure IIS Web Farm Load Balancing
- Step 4: Configure SSL Central Certificate Store
- Step 5: Configure Application Deployment

After you have completed these planning steps, see Configure a Web Farm with IIS Servers. For more information, see Build a Web Farm with IIS Servers.

Step 1: Install IIS Web Farm Infrastructure

The first step in installing and configuring an IIS 8 web farm is to install IIS on the web servers and load balancing server. Then install Application Request Routing (ARR) on the load balancing server. Finally, set up your website on one of the web servers. The goal of this step is to get the software you need installed on your servers. You configure your web farm later in the process.

The following list shows the tasks required to complete this step:

1.1. Install IIS with Appropriate Modules

1.2 Install ARR for Load Balancing

1.3 Set up Your Website on One Web Server

When you are done with these tasks, record your design decisions before going on to Step 2: Configure IIS Web Farm Servers.

1.1. Install IIS with Appropriate Modules

Install IIS on all servers in your web farm except your back-end file servers (content server and certificate store server). The ARR server requires only a default install of IIS with **Centralized SLL Certificate Support**. All of the web servers require you to install IIS and all IIS modules that support the types of web applications you intend to run.

To install IIS on an ARR server

1. On the **Start** page, click the **Server Manager** tile, and then click **OK**.
2. In **Server Manager**, select **Dashboard**, and click **Add roles and features**.
3. In the **Add Roles and Features Wizard**, on the **Before You Begin** page, click **Next**.
4. On the **Select Installation Type** page, select **Role-based or Feature-based Installation** and click **Next**
5. On the **Select Destination Server** page, select **Select a server from the server pool**, select the name of your computer, and click **Next**.
6. On the **Select Server Roles** page, select **Web Server (IIS)**, and then click **Next**.
7. On the **Select Features** page, notice the preselected features, and then click **Next**.
8. On the **Web Server Role (IIS)** page, click **Next**.
9. On the **Select Features** page, note the preselected features that are installed by default, and then select **Centralized SSL Certificate Support** under the **Security** node.
10. Click **Next**.
11. On the **Confirm Installation Selections** page, confirm your selections, and then click **Install**.
12. On the **Installation Progress** page, confirm that your installation of the Web Server (IIS) role and required role services completed successfully, and then click **Close**.
13. To verify that IIS installed successfully, enter the following into a web browser:

    http://localhost

    You see the default IIS Welcome page.

To install IIS and IIS modules on web servers

1. On the **Start** page, click the **Server Manager** tile, and then click **OK**.
2. In **Server Manager**, select **Dashboard**, and click **Add roles and features**.
3. In the **Add Roles and Features Wizard**, on the **Before You Begin** page, click **Next**.
4. On the **Select Installation Type** page, select **Role-based or Feature-based Installation** and click **Next**
5. On the **Select Destination Server** page, select **Select a server from the server pool**, select your server, and click **Next**.

6. On the **Select Server Roles** page, select **Web Server (IIS)**, and then click **Next**.
7. On the **Select Features** page, note the preselected features that are installed by default, and then select additional role services for the type of web applications you plan to support.

   Caution
   Install only the role services your websites require. This practice increases your website security.
8. Click **Next**.
9. On the **Web Server Role (IIS)** page, click **Next**.
10. On the **Select Role Services** page, note the preselected role services that are installed by default, and then click **Next**.

    Note
    You only have to install the IIS 8 default role services for a static-content web server.
11. On the **Confirm Installation Selections** page, confirm your selections, and then click **Install**.
12. On the **Installation Progress** page, confirm that your installation of the Web Server (IIS) role and required role services completed successfully, and then click **Close**.
13. To verify that IIS installed successfully, type the following into a web browser:

    http://localhost

    You should see the default IIS Welcome page.

1.2 Install ARR for Load Balancing

Once you have a default installation of IIS on a server, you can use Web Platform Installer to install the current version of Application Request Routing (ARR).

To install ARR load balancing and its dependencies

1. Open a browser to the Application Request Routing website, and click the **Install** button.
2. Click **Allow**, and then click **Yes**.
3. In the **Web Platform Installer** window, click **Install**.
4. Look over the components to be installed, and then click **I Accept**.

   When the installer completes the installation, it displays and summary showing what was installed.
5. Click **Finish**, and then click **Exit**.

1.3 Set up Your Website on One Web Server

Before you proceed to the next step, set up and test your web application on one of your web servers. This will make configuring shared configuration and shared content much easier.

If you need help configuring your website on your web server, refer to one of the following IIS scenarios:

1. Build a Static Website on IIS
2. Build a Classic ASP Website on IIS
3. Build an ASP.NET Website on IIS
4. Build a PHP Website on IIS
5. Build an FTP Site on IIS

- Step 4: Plan SSL Central Certificate Store
- Configure a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 2: Configure IIS Web Farm Servers

In the second phase of building your web farm, you configure shared content and shared configuration on your first web server. Then you add more web servers to your farm.

The following list shows the tasks required to complete this step:

2.1. Prepare Your Back-end File Server

2.2. Configure Shared Content

2.3. Set up Shared Configuration

2.4. Add Web Servers to Your Farm

When you are done with these tasks, record your design decisions before going on to Step 3: Configure IIS Web Farm Load Balancing.

2.1. Prepare Your Back-end File Server

In this procedure, you set up a back-end file server with two shared folders. One folder contains the shared content files for the website. The other folder contains the shared configuration files.

Once the shared content folder is ready, copy the files for the website you set up on the primary web server to the content folder.

To set up your back-end file server

1. On the file server, open Windows Explorer.
2. Create a folder for the shared content, for example `C:\Content`.
3. Create a folder for the shared configuration, fox example `C:\Config`.
4. Share the content folder by using the custom user credentials.
5. Share the configuration folder by using the custom user credentials.
6. Copy the files from the working website on your primary web server to the content folder on the file server, for example `C:\Content\MySite`.

2.2. Configure Shared Content

In this procedure, you set up shared content of your primary web server. When finished, your web server retrieves content from the back-end file server.

To configure shared content

1. On your primary, open IIS Manager, select you website, and click **Advanced Settings** in the **Actions** pane.
2. On the **Advancing Settings** page, change the value of **Physical Path** to the configuration UNC path, for example `\\FileServer\Content\MySite`.
3. Select **Physical Path Credentials**, and click the ellipsis (…) button.
4. In the **Connect As** dialog, select **Specific user**, and click **Set**.
5. Enter the credentials of the custom shared user account, and click **OK**.
6. Click **OK** two more times to exit **Advanced Settings**.
7. If your web farm supports ASP.NET, open command prompt, and enter one the following commands depending on your system:
   - 64-bit systems: `cd %windir%\Microsoft.NET\Framework64\v4.030319`
   - 32-bit systems: `cd %windir%\Microsoft.NET\Framework\v4.030319`
8. Enter the following command:

   ```
   caspol –m –ag 1. –url file://<file server>/<content>/<website>/* FullTrust
   ```

   Replace `<file server>` with the name of your file server. Replace `<content>` with the name of your shared content folder. Replace `<website>` with the folder name for your website. Note **FullTrust** is case-sensitive.
9. Close the command prompt, select **Application Pools** in the **Connections** page.
10. Select the application pool for your site, and click **Recycle** in the **Actions** pane.
11. Open a browser, view your site with **localhost**. The site is displayed as usual, but the content is coming from the back-end file server.

2.3. Set up Shared Configuration

To configure shared configuration, export the configuration files to the back-end file server. Then point the web server to the shared configuration location.

To set up shared configuration

1. Open IIS Manager, select your server name, and double-click **Shared Configuration**.
2. In the **Actions** pane, click **Export Configuration**.
3. In the **Physical path** box, type the UNC path for the shared configuration folder on the file server, for example `\\FileServer\Config`.
4. Click **Connect As**.
5. Enter the credentials of the custom shared user account, and click **OK**.
6. Under **Encryption Keys**, type a password for encryption the configuration files, and confirm the password.
7. Click **OK**.
8. On the Shared Configuration page, select the **Enable shared configuration** check box.
9. In the **Physical path** box, type the UNC path to the configuration folder on the file server.
10. In the **User name** box, type the custom shared user name.
11. In the **Password** and **Confirm password** boxes, type the password for the custom share user account.
12. In the **Actions** pane, click **Apply**.
13. In the **Encryption Keys Password** dialog, type the encryption keys password and click **OK**.
14. Close IIS Manager, and reopen it.

    IIS is now using the configuration files that are located of the file server.

2.4. Add Web Servers to Your Farm

A web server added to your farm by using this procedure retrieves both configuration information and website content from the back-end file server.

To add a web server to your farm

1. Open IIS Manager, select your server name, and double-click **Shared Configuration**.
2. On the Shared Configuration page, select the **Enable shared configuration** check box.
3. In the **Physical path** box, type the UNC path to the configuration folder on the file server.
4. In the **User name** box, type the custom shared user name.
5. In the **Password** and **Confirm password** boxes, type the password for the custom share user account.
6. In the **Actions** pane, click **Apply**.
7. In the **Encryption Keys Password** dialog, type the encryption keys password and click

OK.

8. Close and reopen IIS Manager.
9. If your web farm supports ASP.NET, open command prompt, and enter one the following commands depending on your system:
   - 64-bit systems: `cd %windir%\Microsoft.NET\Framework64\v4.030319`
   - 32-bit systems: `cd %windir%\Microsoft.NET\Framework\v4.030319`
10. Enter the following command:

    ```
    caspol –m –ag 1. –url file://<file server>/<content>/<website>/* FullTrust
    ```

    Replace `<file server>` with the name of your file server. Replace `<content>` with the name of your shared content folder. Replace `<website>` with the folder name for your website. Note **FullTrust** is case-sensitive.
11. Close the command prompt, select **Application Pools** in the **Connections** page.
12. Select the application pool for your site, and click **Recycle** in the **Actions** pane.
13. Open a browser, view your site with **localhost**. The site displays like it did on the primary server.

- Step 1: Install IIS Web Farm Infrastructure
- Step 2: Plan IIS Web Farm Configuration
- Configure a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 3: Configure IIS Web Farm Load Balancing

Now that IIS is installed all web servers. All web servers share both contend and configuration. And IIS and ARR are installed on your load balancing server. It is time to configure ARR and turn your servers into a functioning web farm.

The following list shows the tasks required to complete this step:

3.1. Create a Server Farm with ARR

3.2. Configure Load Balancing with ARR

3.3. Change Application Pool Settings

When you are done with these tasks, record your design decisions before going on to Step 4: Configure SSL Central Certificate Store.

3.1. Create a Server Farm with ARR

To create your server farm, you must enter the IP address of every web server in your farm.

To create a server farm with ARR

1. Open IIS Manager.
2. In the **Connections** pane, expand the server node, and select **Server Farms**.
3. In the **Actions** pane, click **Create Server Farm**.

   The **Create Server Farm** wizard opens to the **Specify Server Farm Name** page.
4. In the **Server farm name** box, type a name for your server farm, and click **Next**.

   The **Add Server** page is displayed.
5. In the **Server address** box, type the IP address of the first server, and click **Add**.
6. Continue typing IP addresses and clicking **Add** until all web servers are entered.
7. Click **Finish**.

3.2. Configure Load Balancing with ARR

This procedure configures ARR load balancing with an algorithm that distributes incoming request evenly among the web servers. It then sets up the server-farm health test feature.

To configure load balancing with ARR

1. Open IIS Manager.
2. In the Connections pane, expend the server
3. Under the server node, expand **Server Farms**, and then select the server farm that you created.
4. In the **Server Farm** pane, double-click **Load Balance**.
5. On the **Load Balance** page, select **Weighted round robin** from the **Load balance algorithm** list, and then click **Apply**.
6. In the **Connections** pane, select the server farm that you created.
7. In the **Server Farm** pane, double-click **Health Test**.
8. On the **Health Test** page, in the **URL** box, enter a URL that you want ARR to test by sending a GET request to determine the health of the servers. Click **Apply**.
9. To verify the health of your farm, click **Verify URL Test**.

3.3. Change Application Pool Settings

Because all HTTP requests and responses go through ARR, delays or errors occur if the application pool times out or recycles unexpectedly. Set the idle time-out and application pool recycle settings to zero to avoid problems.

To change application pool settings

1. On one of the web servers in your farm, open IIS Manager.
2. In the **Connections** pane, select **Application Pools**.
3. In the **Application Pools** pane, select the application pool for you website, and then click **Advanced Settings** in the **Actions** pane.
4. In the **Advanced Settings** dialog box, expand **Process Model**, and change the **Idle Time-out (minutes)** value to 0.
5. Expand **Recycling**, and change the **Regular time intervals (in minutes)** value to 0.
6. Click **OK**.

- Step 4: Configure SSL Central Certificate Store
- Step 2: Configure IIS Web Farm Servers
- Step 3: Plan IIS Web Farm Load Balancing
- Configure a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 4: Configure SSL Central Certificate Store

In the final phase of building a web farm with IIS servers, you add a central certificate store to your farm. This store enables you to place your SSL certificates on one file server and share them with all web servers in farm. You no longer have to have copies of every certificate on every server.

This article guides you through configuring a central certificate store and testing it on your web farm.

The following list shows the tasks required to complete this step:

4.1. Configure a Central Certificate Store

When you are done with these tasks, record your design decisions before going on to Step 5: Configure Application Deployment.

4.1. Configure a Central Certificate Store

Before attempting to configure a central certificate store, create a shared folder on a dedicated back-end file server. You must provide a UNC path to the shared folder (for example, \\CertServer\Certs).

To configure a central certificate store

1. On your ARR server, open IIS Manager.
2. In the **Connections** pane, select the server node.
3. Double-click **Centralized Certificates**.
4. In the **Actions** pane, click **Edit Feature Settings**.
5. In the **Edit Centralized Certificates Settings** dialog, select the **Enable Centralized Certificates** check box.
6. In the **Physical path** box, type the UNC path to the shared certificate folder.
7. In the **User name** box, type the name of the custom user account on the file server.
8. In the **Password** and **Confirm password** boxes, type the password for the account.
9. If your certificates use a private key password, type the password in the **Password** and **Confirm password** boxes.
10. Click **OK**.

- Step 5: Configure Application Deployment
- Step 4: Plan SSL Central Certificate Store
- Configure a Web Farm with IIS Servers
- Build a Web Farm with IIS Servers
- Hosting-Friendly Web Server Platform (IIS): Scenario Overview

Step 5: Configure Application Deployment

In this step of building a web farm, you install and configure FTP for deploying website updates and new websites. You also install and configure Web Deploy for deploying web applications.

The following list shows the tasks required to complete this step:

5.1. Install and Configure FTP for Your Web Farm

5.2. Install and Test Web Deploy for Your Web Farm

5.3. Where do I go from here?

5.1. Install and Configure FTP for Your Web Farm

The procedures in this section guide you through installing and configuring FTP for your web farm. Install FTP on your load balancing computer (ARR server) only. The web servers do not need FTP installed. For more information about FTP configuration, see Build an FTP Site on IIS.

To install FTP for your farm

1. On the **Start** screen, and click the **Server Manager** tile.
2. In the **Server Manager Dashboard**, click **Add roles and features**.
3. If the **Before you begin** page of **Add Roles and Features Wizard** is displayed, click **Next**.
4. On the **Select installation type** page, select **Role-based or feature-based installation**, and click **Next**.
5. On the **Select destination server** page, select **Select a server from the server pool**, select your server from the **Server Pool** list, and then click **Next**.
6. On the **Select server roles** page, expand the **Web Server (IIS)** node, and then expand the **FTP Server** node.
7. Select the **FTP Server** check box and the **FTP Service** check box, and then click **Next**.
8. On the **Select features** page, click **Next**.
9. On the **Confirm installation selections** page, click **Install**.

To add an FTP site

1. Open IIS Manager.
2. In the **Connections** pane, expand the server node and click the **Sites** node.
3. In the **Actions** pane, click **Add FTP Site** to open the **Add FTP Site** wizard.
4. On the **Site Information** page, in the **FTP site name** box, type a unique friendly name for the FTP site.
5. In the **Physical path** box, type the UNC path to the shared content folder on your back-end file server.
6. Click **Next** to open the **Binding and SSL Settings** page.
7. Under **Binding**, in the **IP Address** list, select or type an IP address if you do not want the IP address to remain **All Unassigned**.
8. In the **Port** box, type the port number.
9. Optionally, in the **Virtual Host** box, type a host name if you want to host multiple FTP sites on a single IP address. For example, type **www.contoso.com**.
10. Clear the **Start FTP site automatically** box if you want to start the site manually.
11. Under **SSL**, from the **SSL Certificate** list, select a certificate. Optionally, click **View** to open the **Certificates** dialog box and verify information about the selected certificate.
12. Select one of the following options:
    - **Allow SSL**: Allows the FTP server to support both non-SSL and SSL connections with a client.
    - **Require SSL**: Requires SSL encryption for communication between the FTP server and a client.
13. Click **Next** to open the **Authentication and Authorization Information** page.
14. Under **Authentication**, select the authentication method or methods that you want to

use:

- **Anonymous**: Allows any user to access content providing only the user name **anonymous** or **ftp**. (Most, but not all, FTP clients enter user name for you automatically.)
- **Basic**: Requires users to provide a valid user name and password to access content. Because Basic authentication transmits unencrypted passwords across the network, use this authentication method only when you know that the connection between the client and FTP server is secure, such as by using Secure Sockets Layer (SSL).

15. Under **Authorization**, from the **Allow access to** list, select one of the following options:
    - **All Users**: All users, whether they are anonymous or identified, can access the content.
    - **Anonymous Users**: Anonymous users can access the content.
    - **Specified Roles or User Groups**: Only members of certain roles or user groups can access the content. Type the role or user group in the corresponding box.
    - **Specified Users**: Only specified users can access the content. Type the user name in the corresponding box.
16. If you selected an option from the **Allow access to** list, select one or both of the following permissions:
    - **Read**: Permits authorized users to read content from the directory.
    - **Write**: Permits authorized users to write to the directory.
17. Click **Finish**.

5.2. Install and Test Web Deploy for Your Web Farm

Install Web Deploy on your source computer (your development computer with IIS installed). Install Web Deploy on each of your web application servers. Use Web Platform Installer to install the current version of Web Deploy and its dependencies.

To test your Web Deploy installation, use it to update your website.

To install Web Deploy for you farm

1. Open a browser to the Web Deployment Tool website, and click the **Install** button.
2. Click **Allow**, and then click **Yes**.
3. In the **Web Platform Installer** window, click **Install**.
4. Look over the components to be installed, and then click **I Accept**.

   When the installer completes the installation, it displays and summary showing what was installed.
5. Click **Finish**, and then click **Exit**.

To update your website with Web Deploy

1. On your development computer, open IIS Manager.
2. In the **Connections** pane, select the updated website.
3. In the **Actions** pane, click **Export Application**.

   The **Export Application Package** wizard appears.
4. On the **Select the Contents of the Package** page, make sure all check boxes are selected, and click **Next**.
5. On the **Select Parameters** page, add parameters if needed for your application, and click **Next**.
6. On the **Save Package** page, type the path (including the package name) to the location where you want the package saved.

   This location could to a shared folder on the development computer or a shared folder on the destination computer (the ARR server).
7. Click **Next**.

   The package is exported and saved.
8. Click **Finish**.
9. On one of your web application servers, open IIS Manager.
10. In the **Actions** page, click **Import Application**.

    The **Import Application Package** appears.
11. On the **Select the Package** page, type the path (including the package name) to the location where you exported the package.
12. Click **Next**.
13. On the **Select the Contents of the Package** page, make sure all check boxes are selected, and click **Next**.
14. On the **Enter Application Package Information** page, type the path to your website, and click **Next**.
15. On the **Overwrite Existing Files** page, choose whether to delete all files that are in the new package, and click **Next**.
16. Click **Finish**.

    Web Deploy has updated your website.

5.3. Where do I go from here?

You now have a working web farm. It uses ARR for load balancing. It employs shared content and shared configuration. You have a central certificate store for use with SSL-secured websites. And you can deploy websites and web applications with either FTP or Web Deploy.

There are many ways to improve your web farm, here are a few suggestions:

- Allow users who are not administrators to deploy web applications with Web Deploy. For more information, see Allowing non-admin users to deploy web applications.
- Use failover clustering to mirror your back-end file servers, eliminate signal points of failure on the back-end, and improve throughput. For more information, see Failover Clustering.

- You should also to eliminate signal points on failure on the front end. You can use Network Load Balancing (NLB) with multiple ARR servers achieve high availability, scalability, and stability on the front end of your farm. To learn more about using ARR and NLB together, see Achieving High Availability and Scalability—ARR and NLB.

Increasing Server, Storage, and Network Availability: Scenario Overview

Server Availability in Windows Server 2012 provides a collection of experiences that are designed to improve availability, performance, and reliability at the single-server and multiple-server (scale-up and scale-out) levels. The experiences in Server Availability include the following:

- **Improved NTFS availability** Install and configure large volumes that are resilient against downtime caused by potential file corruption.
- **File server for scale-out application data** Deploy server applications, such as Microsoft SQL Server and Hyper-V, on continuously available file servers.
- **Continuously available DHCP service** Improve network availability by using Dynamic Host Configuration Protocol (DHCP) failover services.
- **Network failure resilience** Use Load Balancing and Failover to aggregate bandwidth and maximize network reliability.
- **Continuously available block storage for server applications** Create continuously available block storage for server applications by using iSCSI Transparent Failover.
- **Fast and efficient file servers for server applications** Improve network and file performance by using Remote Direct Memory Access (RDMA) and SMB Direct.
- **Network performance and availability for Windows file servers** Take advantage of all available network bandwidth by using SMB Multichannel.
- **Storage spaces** Enable cost-effective and flexible storage solutions for business critical deployments.
- **Offloaded data transfers** Move data quickly between storage devices by using Offloaded Data Transfer.

- **Storage mobility for virtual machines** Move virtual hard disks to other locations with no downtime.
- **Direct connections for virtualized workloads to Fibre Channel-based storage** Provide server applications with access to Fibre Channel-based storage directly from a guest operating system.
- **Continuously available file servers for heterogeneous environments** Create continuously available Network File System (NFS) file shares by using NFS transparent failover.
- **Data protection** Protect your application data by using SMB Volume Shadow Copy for remote file shares.
- **Hyper-V over SMB** Enable virtual machines to reside on an SMB file shares, giving you the power to design new flexible storage solutions for your virtual or cloud infrastructure.

Deploying Fast and Efficient File Servers for Server Applications

This document outlines the planning and deployment steps for setting up fast and efficient file servers for server applications, such as Hyper-V™ and Microsoft SQL Server.

Overview

In Windows Server® 2012, the SMB protocol for remote storage has been enhanced to allow for faster and more efficient file servers for server applications, such as Hyper-V and SQL Server. As part of the SMB protocol, two new features, SMB Direct and SMB Multichannel, enable customers to deploy storage for server applications on cost efficient, continuously available, high performance file servers.

SMB Direct supports the use of network adapters that have remote direct memory access (RDMA) capability. SMB Direct (SMB over RDMA) is a new storage protocol in Windows Server 2012 that includes:

- **Increased throughput**: Leverages the full throughput of high speed networks where the network adapters coordinate the transfer of large amounts of data at line speed.
- **Low latency**: Provides extremely fast responses to network requests, and, as a result, makes remote file storage feel as if it is directly attached block storage.
- **Low CPU utilization**: Uses fewer CPU cycles when transferring data over the network, which leaves more power available to server applications.

SMB Direct is automatically configured by Windows Server 2012.

SMB Multichannel allows file servers to use multiple network connections simultaneously and includes the following capabilities:

- **Fault tolerance**. When using multiple network connections at the same time, the file server continues functioning despite the loss of a network connection.
- **Increased throughput**. The file server can simultaneously transmit more data using multiple connections for high speed network adapters or multiple network adapters.

SMB Multichannel is automatically configured by Windows Server 2012.

Requirements and recommendations

Before deploying the file server, you should review the requirements and recommendations outlined below.

SMB Direct

SMB Direct requires the following:

- At least two computers running Windows Server 2012

- A network adapter with RDMA capability. Currently, these network adapters are available in three different types: iWARP, Infiniband, or RoCE (RDMA over Converged Ethernet).

SMB Multichannel

SMB Multichannel requires the following:

- At least two computers running Windows Server 2012 or Windows RT.
- At least one of the configurations below:

  Multiple network adapters

  One or more network adapters that support RSS (Receive Side Scaling)

  One or more network adapters that support RDMA

The following are sample network configurations that can be used for SMB Multichannel:

- **Single 10 GbE network adapter**. Each computer is configured with a 10 GbE network adapter, which is RSS-capable or RDMA-capable.
- **Dual 1 GbE network adapters configured in a team**. Each computer is configured with two 1 gigabit Ethernet network adapters in a load balancing and failover environment, also known as a network adapter team.
- **Dual 1 GbE network adapters**. Each computer is configured with dual 1 gigabit Ethernet network adapters.
- **Dual 10 GbE network adapters**. Each computer is configured with dual 10 GbE network adapters. These adapters could also be RSS-capable and/or RDMA-capable.
- **Dual Infiniband network adapters**. Each computer is configured with dual Infiniband network adapters. These adapters are typically RDMA-capable.

Install the required roles, role services, and features

By default, both SMB Multichannel and SMB Direct are enabled on Windows Server 2012. You do not need to add any roles, role services, or features to utilize the functionality of SMB Multichannel and SMB Direct. For information on installing roles, role services, and features, see “Step 1: Install Prerequisites for Scale-out File Servers” in Deploy Scale-Out File Server.

Step-by-step instructions

Use the following steps to validate a configuration that leverages SMB Multichannel or SMB Direct. Both SMB Multichannel and SMB Direct can be used with different file server configurations, including standalone file server clusters or Scale-Out file server clusters. In this document, the focus is on the Scale-out File Server cluster configuration.

- Step 1: Verify the basic network configuration
- Step 2: Configure a failover cluster
- Step 3: Configure the networks for the failover cluster

- Step 4: Configure a Scale-out File Server
- Step 5: Verify each file server name has two addresses
- Step 6: Configure a Hyper-V or Microsoft SQL Server client
- Step 7: Verify servers are using SMB Multichannel and SMB Direct
- Step 8: Monitor file shares using Performance Counters

Step 1: Verify the basic network configuration

After installing Windows Server 2012, you can use the following Windows PowerShell commands to verify the network adapters that are configured. If you are using RSS-capable and/or RDMA-capable network adapters, you can verify that these capabilities are being properly detected.

To verify the basic network configuration

1. Open **Windows PowerShell**.
2. On each server, type the following to view a list of network adapters:

   ```
   Get-NetAdapter
   ```

   Review the list of network adapters installed on the system, along with their basic characteristics. You should have at least two adapters configured.
3. On each server, type the following to view a list of network adapters available to SMB:

   ```
   Get-SmbServerNetworkInterface
   ```

   Review the list of network adapters, and note whether they are RSS-capable and/or RDMA-capable. You should have at least two adapters configured.
4. You can also verify the network configuration using Server Manager. In Server Manager, click **Local Server** and verify that you have at least two network adapters configured for the server.

Step 2: Configure a failover cluster

For instructions on configuring a failover cluster in Windows Server 2012, see Deploy Scale-Out File Server.

Step 3: Configure the networks for the failover cluster

In this example, use two networks in your failover cluster, which allows you to use SMB Multichannel in a two network adapter configuration. You should enable two of the networks on the failover cluster for client access.

To configure the networks using Failover Cluster Manager

1. From one of the cluster nodes, open Server Manager.
2. In the Server Manager menu bar, click **Tools** to access the contents of the **Administrative Tools** folder. Select **Failover Cluster Manager** from the list of tools.

3. On the left pane in Failover Cluster Manager, click to expand the failover cluster you want to use, and then click **Networks**.
4. Right-click the cluster network you want to configure, and click **Properties**.
5. Make sure both **Allow cluster network communication on this network** and the checkbox next to **Allow clients to connect through this network** are selected.
6. Repeat, as required, so that two of the cluster networks are configured with both of these properties.

To configure the networks using Windows PowerShell

1. Open **Windows PowerShell**.
2. From one of the cluster nodes, type the following to configure the networks:

   ```
   Get-ClusterNetwork
   ```

   The list of networks available to the failover cluster is displayed, along with their role.
3. From the cluster node, type the following to specify client access:

   ```
   (Get-ClusterNetwork <NetworkName>).Role = 3
   ```

   The specified cluster network is configured for client access. You should repeat this step for two of the networks that are listed.

Step 4: Configure a Scale-out File Server

For instructions on configuring a Scale-out File Server in Windows Server 2012, see Deploy Scale-Out File Server.

Step 5: Verify each file server name has two addresses

In this example, confirm that the Scale-out File Server is properly configured for SMB Multichannel by verifying that you have two network adapters configured for the Scale-out File Server name. If you are using RDMA network adapters, you can also verify if these are properly configured.

To configure the networks using Windows PowerShell

1. Open **Windows PowerShell**.
2. From one of the file servers, type the following:

   ```
   Get-ClusterNetwork
   ```

   The list of networks available to the failover cluster is displayed, along with their role.
3. From the cluster node, type the following to specify client access:

   ```
   Get-SmbServerNetworkInterface
   ```

   In addition to the list of network interfaces you viewed in Step 1, you should see additional entries for the file server name you have created. You should have at least two network adapters configured for the file server name, and you can also verify if they are

RSS-capable and/or RDMA-capable.

Step 6: Configure a Hyper-V or Microsoft SQL Server client

To configure Hyper-V or Microsoft SQL Server as a client for your Scale-out File Server, see Deploy Scale-Out File Server.

Step 7: Verify servers are using SMB Multichannel and SMB Direct

In this example, confirm that the application server (running either Hyper-V or Microsoft SQL Server) is properly leveraging the two network adapters using SMB Multichannel. If you are using RDMA adapters, you can also verify if you are using SMB Direct.

To verify that the servers are using SMB Multichannel and SMB Direct

1. Open **Windows PowerShell**.
2. On the application server using SMB, type the following:

   ```
   Get-SmbClientNetworkInterface
   ```

   The list of network adapters available to the SMB Client is displayed, along with the indication on whether they are RSS-capable and/or RDMA-capable.
3. On the application server using SMB, type the following:

   ```
   Get-SmbMultichannelConnection
   ```

   You can view the connections that are actively used for the currently established sessions, and you can also verify if they are RSS-capable and/or RDMA-capable. You should have two paths listed for the Scale-out File Server name.

   Note
   When you use this cmdlet, it will not show any information unless the application server is actively accessing the file server.

Step 8: Monitor file shares using Performance Counters

In Windows Server 2012, new SMB performance counters provide detailed information about I/O size, I/O latency, and IOPS, allowing administrators to analyze the performance of SMB file shares where their data is stored. These counters are specifically designed for server applications, such as Hyper-V and SQL Server, which store files on remote Windows file shares.

To monitor application server activity on the SMB share

1. In the Server Manager menu bar, click **Tools** to access the contents of the **Administrative Tools** folder. Select **Performance Monitor** from the list of tools.
2. Under **Performance**, and then under **Monitoring Tools**, click **Performance Monitor**.
3. Right-click in the Performance Monitor window, and click **Add Counters**. You can also

do this by pressing CTRL+N.

4. To view activity for virtual machines, under **Available counters**, expand **SMB2 Client Shares** and select all of the counters.
5. Select the share used by the application server, and click **Add**. Click **OK** to continue.
6. On the Taskbar, click **Change graph type** to change the type to **Report**. You can also do this by pressing CTRL+G twice.
7. You can now view the activity of the counters in the Performance Monitor window.

Scale-Out File Server for Application Data Overview

Scale-Out File Server is a feature that is designed to provide scale-out file shares that are continuously available for file-based server application storage. Scale-out file shares provides the ability to share the same folder from multiple nodes of the same cluster. This scenario focuses on how to plan for and deploy Scale-Out File Server.

You can deploy and configure a clustered file server by using either of the following methods:

- **Scale-Out File Server for application data** This clustered file server feature was introduced in Windows Server 2012, and it lets you store server application data, such as Hyper-V virtual machine files, on file shares, and obtain a similar level of reliability, availability, manageability, and high performance that you would expect from a storage area network. All file shares are simultaneously online on all nodes. File shares associated with this type of clustered file server are called scale-out file shares. This is sometimes referred to as active-active. This is the recommended file server type when deploying either Hyper-V over Server Message Block (SMB) or Microsoft SQL Server over SMB.
- **File Server for general use** This is the continuation of the clustered file server that has been supported in Windows Server since the introduction of Failover Clustering. This type of clustered file server, and therefore all the shares associated with the clustered file server, is online on one node at a time. This is sometimes referred to as active-passive or dual-active. File shares associated with this type of clustered file server are called clustered file shares. This is the recommended file server type when deploying information worker scenarios.

Scenario description

With scale-out file shares, you can share the same folder from multiple nodes of a cluster. For instance, if you have a four-node file server cluster that is using Server Message Block (SMB) Scale-Out, a computer running Windows Server 2012 R2 or Windows Server 2012 can access

file shares from any of the four nodes. This is achieved by leveraging new Windows Server Failover Clustering features and the capabilities of the Windows file server protocol, SMB 3.0. File server administrators can provide scale-out file shares and continuously available file services to server applications and respond to increased demands quickly by simply bringing more servers online. All of this can be done in a production environment, and it is completely transparent to the server application.

Key benefits provided by Scale-Out File Server in include:

- **Active-Active file shares** All cluster nodes can accept and serve SMB client requests. By making the file share content accessible through all cluster nodes simultaneously, SMB 3.0 clusters and clients cooperate to provide transparent failover to alternative cluster nodes during planned maintenance and unplanned failures with service interruption.
- **Increased bandwidth** The maximum share bandwidth is the total bandwidth of all file server cluster nodes. Unlike previous versions of Windows Server, the total bandwidth is no longer constrained to the bandwidth of a single cluster node; but rather, the capability of the backing storage system defines the constraints. You can increase the total bandwidth by adding nodes.
- **CHKDSK with zero downtime** CHKDSK in Windows Server 2012 is significantly enhanced to dramatically shorten the time a file system is offline for repair. Clustered shared volumes (CSVs) take this one step further by eliminating the offline phase. A CSV File System (CSVFS) can use CHKDSK without impacting applications with open handles on the file system.
- **Clustered Shared Volume cache** CSVs in Windows Server 2012 introduces support for a Read cache, which can significantly improve performance in certain scenarios, such as in Virtual Desktop Infrastructure (VDI).
- **Simpler management** With Scale-Out File Server, you create the scale-out file servers, and then add the necessary CSVs and file shares. It is no longer necessary to create multiple clustered file servers, each with separate cluster disks, and then develop placement policies to ensure activity on each cluster node.
- **Automatic rebalancing of Scale-Out File Server clients** In Windows Server 2012 R2, automatic rebalancing improves scalability and manageability for scale-out file servers. SMB client connections are tracked per file share (instead of per server), and clients are then redirected to the cluster node with the best access to the volume used by the file share. This improves efficiency by reducing redirection traffic between file server nodes. Clients are redirected following an initial connection and when cluster storage is reconfigured.

In this scenario

The following topics are available to help you deploy a Scale-Out File Server:

- Plan for Scale-Out File Server

  Step 1: Plan for Storage in Scale-Out File Server

  Step 2: Plan for Networking in Scale-Out File Server
- Deploy Scale-Out File Server

  Step 1: Install Prerequisites for Scale-Out File Server

Step 2: Configure Scale-Out File Server

Step 3: Configure Hyper-V to Use Scale-Out File Server

Step 4: Configure Microsoft SQL Server to Use Scale-Out File Server

When to use Scale-Out File Server

You should not use Scale-Out File Server if your workload generates a high number of metadata operations, such as opening files, closing files, creating new files, or renaming existing files. A typical information worker would generate a lot of metadata operations. You should use a Scale-Out File Server if you are interested in the scalability and simplicity that it offers and if you only require technologies that are supported with Scale-Out File Server.

The following table lists the capabilities in SMB 3.0, the common Windows file systems, file server data management technologies, and common workloads. You can see whether the technology is supported with Scale-Out File Server, or if it requires a traditional clustered file server (also known as a file server for general use).

Technology	File Server for General Use	Scale-Out File Server
SMB capability: SMB Transparent Failover	Yes	Yes
SMB capability: SMB Scale Out	No	Yes
SMB capability: SMB Multichannel	Yes	Yes
SMB capability: SMB Direct	Yes	Yes
SMB capability: SMB Encryption	Yes	Yes
File system: NTFS file system	Yes	No
File system: Resilient File System (ReFS)	Yes	No
File system: CSV File System (CSVFS)	No	Yes
Data management: BranchCache	Yes	No
Data management: Data Deduplication	Yes	Yes **Warning** In Windows Server 2012 R2, Data Deduplication is

Technology	File Server for General Use	Scale-Out File Server
		only supported in a scale-out file server deployment for Virtual Desktop Infrastructure (VDI) workloads with separate storage and compute nodes. The storage must be remote.
Data management: DFS Namespaces: Namespace Server	Yes	No
Data management: DFS Namespaces: Folder Target	Yes	Yes
Data management: DFS Replication	Yes	No
Data management: File Server Resource Manager	Yes	No
Data management: File Classification Infrastructure	Yes	No
Data management: File Server Volume Shadow Copy Service (VSS) Agent	Yes	Yes
Data management: Folder Redirection	Yes	Yes
Data management: Client-Side Caching	Yes	Yes
Workload: Information worker	Yes	Not recommended
Workload: Hyper-V	Yes	Yes
Workload: Microsoft SQL Server	Yes	Yes

Practical applications

Scale-Out File Servers are ideal for server applications that keep files open for a long amount of time, doing mostly data operations with infrequent metadata operations on the file system. Hyper-V virtual hard disks and SQL Server database files can be stored on a scale-out file share.

Features included in this scenario

The following table lists the features that are part of this scenario and describes how they support it.

Feature	How it supports this scenario
Failover Clustering Overview	Failover clusters added the following features in Windows Server 2012 to support scale-Out file server: Distributed Network Name, the Scale-Out File Server resource type, Cluster Shared Volumes (CSV) 2, and the Scale-Out File Server High Availability role. For more information about these features, see What's New in Failover Clustering in Windows Server 2012 on Microsoft TechNet.
Server Message Block overview	SMB 3.0 added the following features in Windows Server 2012 to support scale-Out File Server: SMB Transparent Failover, SMB Multichannel, and SMB Direct. For more information on new and changed functionality for SMB in Windows Server 2012 R2, see What's New in SMB in Windows Server 2012 R2.

Plan for Scale-Out File Server

Before you deploy Scale-Out File Server, you should review the requirements and plan for the deployment. The information you should review includes:

Failover Clustering requirements Because a Scale-Out File Server is built on Failover Clustering, any requirements for Failover Clustering also apply to Scale-Out File Server.

Server application storage requirements Microsoft SQL Server and Hyper-V are the two server applications that are supported by Scale-Out File Server for storage. You should review the storage requirements for the server application you plan to use.

Existing storage in your organization You can use storage that may already be deployed within your organization.

Network configuration You should review your network adapter configuration, the bandwidth of the CSV redirection traffic, and the DNS configuration for the cluster nodes.

Use the following steps to plan a Scale-Out File Server deployment in your organization:

- Step 1: Plan for Storage in Scale-Out File Server
- Step 2: Plan for Networking in Scale-Out File Server

See also

After you have completed these planning steps, see Deploy Scale-Out File Server.

Scale-Out File Server for Application Data Overview.

Step 1: Plan for Storage in Scale-Out File Server

When you plan the storage that will support your scale-out file server, you can leverage the existing storage in your organization.

Note

Before you deploy Scale-Out File Server, you should review the storage requirements for the server applications that will use Scale-Out File Server.

After you complete this step, see Step 2: Plan for Networking in Scale-Out File Server.

This topic includes the sections that are outlined in the following table, and it can help you through the process of identifying requirements for the server applications in your organization and identifying existing storage that you can leverage.

Task	Description
Review Failover Clustering requirements	Scale-Out File Server uses the features and functionality that are included with Failover Clustering. You should review the requirements for Failover Clustering when planning for a scale-out file server.
Review server application storage requirements	Microsoft SQL Server and Hyper-V are server applications that are supported with Scale-Out File Server. If you plan to store your database files, database transaction logs, or virtual hard disks on scale-out file shares, the same storage recommendations for their respective server

Task	Description
	applications apply.
Review existing storage in your organization	You can use the storage that has already been deployed within your organization.

Review Failover Clustering requirements

Scale-Out File Server is built on Failover Clustering, so any requirements for Failover Clustering also apply to Scale-Out File Server. You should have an understanding of Failover Clustering before deploying Scale-Out File Server. For more information about Failover Clustering, see:

- Use Cluster Shared Volumes in a Failover Cluster
- Installing the Failover Cluster Feature and Tools in Windows Server 2012
- Creating a Windows Server 2012 Failover Cluster
- How to Troubleshoot Create Cluster failures in Windows Server 2012

Some important considerations for Failover Clustering and Scale-Out File Server are as follows:

- The storage configuration must be supported by Failover Clustering before you deploy Scale-Out File Server. You must successfully run the Cluster Validation Wizard before you add Scale-Out File Server.
- Scale-Out File Server requires the use of Clustered Shared Volumes (CSVs).
- Scale-Out File Server is not supported for use with Resilient File System.
- Accessing a continuously available file share as a loopback share is not supported. For example, if Microsoft SQL Server or Hyper-V store data files on SMB file shares, they must run on computers that are not a member of the file server cluster for the SMB file shares.

Review server application storage requirements

Microsoft SQL Server and Hyper-V are the two server applications that are supported by Scale-Out File Server. If you choose to use Microsoft SQL Server or Hyper-V with Scale-Out File Server, the storage recommendations for direct-attached storage apply. For more information about storage requirements, see:

- SQL Server Best Practices Article
- Analyzing I/O Characteristics and Sizing Storage Systems for SQL Server Database Applications

Review existing storage in your organization

It is not necessary to deploy new storage in your organization to support Scale-Out File Server. You can use existing storage that may already be deployed within your organization. Some supported storage configurations that can be used as the storage subsystem for Scale-Out File Server include:

- **Storage Spaces** Storage Spaces was introduced in Windows Server 2012.

  For more information, see Storage Spaces Overview.
- **iSCSI Storage Area Network**

  For more information about iSCSI in Windows Server 2012, see iSCSI Target Block Storage Overview.
- **Fibre Channel Storage Area Network**

  For more information about using a Fibre Channel SAN, see Failover Clustering Hardware Requirements and Storage Options.
- **Clustered RAID controller**

  For more information, see Enable Support for Clustered Windows Servers using clustered RAID controllers.

- Step 2: Plan for Networking in Scale-Out File Server
- Plan for Scale-Out File Server
- Scale-Out File Server for Application Data Overview
- Increasing Server, Storage, and Network Availability: Scenario Overview

Step 2: Plan for Networking in Scale-Out File Server

Networking planning for Scale-Out File Server includes reviewing the network adapter configuration, ensuring that the CSV redirection traffic network bandwidth is sufficient, and that DNS dynamic update protocol is being used for Scale-Out File Server.

Use the following table to help you review the configuration of your network to ensure that it will work when deploying Scale-Out File Server.

Task	Description
2.1. Review your network adapter configurations	Ensure that the network adapter configurations are consistent across all of your nodes in Scale-Out File Server.
2.2. Review the CSV redirection traffic network configuration	Ensure that the network that includes the CSV redirection traffic has sufficient bandwidth.
2.3. Review the DNS configuration for the cluster nodes	Use DNS dynamic update protocol for the cluster node name and all of the cluster nodes.

2.1. Review your network adapter configurations

The network adapters in each of the cluster nodes for the Scale-Out File Server should be the same. For more information on the different options that are available, see Deploying Fast and Efficient File Servers for Server Applications.

2.2. Review the CSV redirection traffic network configuration

The network containing the CSV redirection traffic must have enough bandwidth to service all requests. If the network bandwidth is not adequate, you could create an internal network for just CSV redirection traffic and use an external network for the rest.

2.3. Review the DNS configuration for the cluster nodes

You should make sure that the cluster node name is registered by using DNS dynamic update protocol. This should include the name of the Scale-Out File Server and the IP addresses of all of the network adapters in every cluster node on the client network.

- Step 1: Plan for Storage in Scale-Out File Server
- Plan for Scale-Out File Server
- Scale-Out File Server for Application Data Overview
- Increasing Server, Storage, and Network Availability: Scenario Overview

Deploy Scale-Out File Server

Use the following steps to deploy Scale-Out File Server in your organization:

- Step 1: Install Prerequisites for Scale-Out File Server
- Step 2: Configure Scale-Out File Server
- Step 3: Configure Hyper-V to Use Scale-Out File Server
- Step 4: Configure Microsoft SQL Server to Use Scale-Out File Server

Important

To take full advantage of Scale-Out File Server, all servers running the server applications that are using scale-out file shares should be running Windows Server 2012 R2 or Windows Server 2012. If the server application is running on Windows Server 2008 or Windows Server 2008 R2, the servers can connect to the scale-out file shares, but they cannot take advantage of any of the new features. If the server application is running

Windows Server 2003, the server receives access-denied error when connecting to the scale-out file share.

Step 1: Install Prerequisites for Scale-Out File Server

Scale-Out File Server leverages features that are included in the File and Storage Services role and in the Failover Clustering feature. You must install the prerequisite features and role services, create a failover cluster, add then add storage to a cluster shared volume.

Task	Description
1.1. Install role services and features	Install the File Server role service and Failover Clustering by using Server Manager or by using Windows PowerShell.
1.2. Validate hardware and create a cluster	Validate the hardware configuration and create a cluster.
1.3. Add storage to a cluster shared volume	A cluster shared volume is required for a scale-out file share.

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

1.1. Install role services and features

The File Server role service, which is part of the File and Storage Services server role, and the Failover Clustering feature are required to configure Scale-Out File Server. You configure these by using Server Manager or by using Windows PowerShell.

Do this step using Windows PowerShell

To install the roles and features

1. Log on to the server as a member of the local Administrators group.
2. Server Manager will start automatically. If it does not automatically start, click **Start**, and then click **Server Manager**.
3. In the **QUICK START** section, click **Add roles and features**.
4. On the **Before you begin** page of the **Add Roles and Features Wizard**, click **Next**.
5. On the **Select installation type** page, click **Role-based or feature-based installation**, and then click **Next**.

6. On the **Select destination server** page, select the appropriate server, and then click **Next**. The local server is selected by default.
7. On the **Select server roles** page, expand **File and Storage Services**, expand **File Services**, and then select the **File Server** check box. Click **Next**.
8. On the **Select features** page, select the **Failover Clustering** check box, and then click **Next**.
9. On the **Confirm installation selections** page, click **Install**.
10. Repeat the steps in this procedure for each server that will be added to the cluster.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Add-WindowsFeature –name File-Services,Failover-Clustering –IncludeManagementTools
```

1.2. Validate hardware and create a cluster

You can ensure that you are using the proper hardware by validating the configuration. After the validation is complete, you can create the cluster.

Do this step using Windows PowerShell

To validate hardware and create a cluster

1. Log on to the server as a member of the local Administrators group.
2. Server Manager will start automatically. If it does not automatically start, click **Start**, and then click **Server Manager**.
3. Click **Tools**, and then click **Failover Cluster Manager**.
4. Under the **Management** heading, click **Validate Configuration**.
5. On the **Before You Begin** page, click **Next**.
6. On the **Select Servers or a Cluster** page, in the **Enter name** box, type the FQDN of one of the servers that will be part of the cluster, and then click **Add**. Repeat this step for each server that will be in the cluster.

   Note
   If you already have a cluster configured, you can enter the name of the cluster or one of its nodes instead of entering the name of each server.
7. Click **Next**.
8. On the **Testing Options** page, ensure that the **Run all tests (recommended)** option is selected, and then click **Next**.
9. On the **Confirmation** page, click **Next**.
10. On the **Summary** page, ensure that the **Create the cluster now using the validated nodes** check box is selected, and then click **Finish**. The Create Cluster Wizard appears.

11. On the **Before You Begin** page, click **Next**.
12. On the **Access Point for Administering the Cluster** page, in the **Cluster Name** box, type a name for the cluster, and then click **Next**.
13. On the **Confirmation** page, click **Next**.
14. On the **Summary** page, click **Finish**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Test-Cluster –Node server1, server2

New-Cluster –Name ClusterName –Node server1, server2
```

1.3. Add storage to a cluster shared volume

A cluster shared volume is used by a failover cluster, and it can be accessed by more than one node at a time. You can add to a cluster shared volume by using Failover Cluster Manager.

Do this step using Windows PowerShell

To add storage to a cluster shared volume

1. Log on to the server as a member of the local Administrators group.
2. Server Manager will start automatically. If it does not automatically start, click **Start**, and then click **Server Manager**.
3. Click **Tools**, and then click **Failover Cluster Manager**.
4. Click **Storage**, right-click the disk that you want to add to the cluster shared volume, and then click **Add to Cluster Shared Volumes**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Add-ClusterSharedVolume "ClusterDiskName"
```

- Step 3: Configure Hyper-V to Use Scale-Out File Server
- Step 4: Configure Microsoft SQL Server to Use Scale-Out File Server
- Deploy Scale-Out File Server
- Scale-Out File Server for Application Data Overview

Step 2: Configure Scale-Out File Server

In this step, you configure Scale-Out File Server for high availability and create a continuously available file share on the cluster shared volume.

Task	Description
Configure Scale-Out File Server	Configure Scale-Out File Server to provide continuous availability for server applications.
Create a continuous availability file share on the cluster shared volume	Create a file share on the cluster shared volume.

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

Configure Scale-Out File Server

Scale-Out File Server must be configured for continuous availability.

To configure the File Server role

1. Sign in to the server as a member of the local Administrators group.
2. To open Failover Cluster Manager in Server Manager, click **Tools**, and then click **Failover Cluster Manager**.
3. Right-click the name of the cluster, and then click **Configure Role**.
4. On the **Before You Begin** page, click **Next**.
5. On the **Select Role** page, click **File Server**, and then click **Next**.
6. On the **File Server Type** page, select the **Scale-Out File Server for application data** option, and then click **Next**.
7. On the **Client Access Point** page, in the **Name** box, type a NETBIOS name that will be used to access Scale-Out File Server, and then click **Next**.
8. On the **Confirmation** page, confirm your settings, and then click **Next**.
9. On the **Summary** page, click **Finish**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
Add-ClusterScaleOutFileServerRole -Name DistributedNetworkName -Cluster ClusterName
```

Create a continuous availability file share on the cluster shared volume

You must create a file share for continuous availability on the cluster shared volume by using Failover Cluster Manager.

Do this step using Windows PowerShell

To create a continuous availability file share on the cluster shared volume

1. Sign in to the server as a member of the local Administrators group.
2. To open Failover Cluster Manager in Server Manager, click **Tools**, and then click **Failover Cluster Manager**.
3. Expand the cluster, and then click **Roles**.
4. Right-click the file server role, and then click **Add File Share**.
5. On **the Select the profile for this share** page, click **SMB Share – Applications**, and then click **Next**.
6. On the **Select the server and path for this share** page, click the name of the cluster shared volume, and then click **Next**.
7. On the **Specify share name** page, in the **Share name** box, type a name for the file share, and then click **Next**.
8. On the **Configure share settings** page, ensure that the **Enable continuous availability** check box is selected, and then click **Next**.

   Note
   You should not use access-based enumeration on file shares for Scale-Out File Server because of the increased metadata traffic that is generated on the coordinator node.
9. On the **Specify permissions to control access** page, click **Customize permissions**, grant the following permissions, and then click **Next**:
   - For Hyper-V: All Hyper-V computer accounts, the SYSTEM account, and all Hyper-V administrators must be granted full control on the share and the file system.
   - For Microsoft SQL Server: The SQL Server service account must be granted full control on the share and the file system.
10. On the **Confirm selections** page, click **Create**.
11. On the **View results** page, click **Close**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

```
New-Item -Name "folder" -ItemType Directory

New-SmbShare -Name ShareName -Path Path -FullAccess Domain\Account
```

```
Set-SmbPathAcl -ShareName ShareName
```

- Step 1: Install Prerequisites for Scale-Out File Server
- Step 3: Configure Hyper-V to Use Scale-Out File Server
- Step 4: Configure Microsoft SQL Server to Use Scale-Out File Server
- Deploy Scale-Out File Server
- Scale-Out File Server for Application Data Overview

Step 3: Configure Hyper-V to Use Scale-Out File Server

Hyper-V is one of two Microsoft applications that are supported when using Scale-Out File Server for data storage. When the failover cluster is configured, virtual machines can be configured by using Hyper-V Manager.

Task	Description
3.1. Verify permissions	Ensure that the permissions on the continuously available file share are configured correctly to host virtual machines.
3.2. Create a new virtual machine	Create a new virtual machine by using Hyper-V Manager.

3.1. Verify permissions

You should ensure that the proper permissions are granted on the continuously available file share before you create the virtual machines.

To verify permissions

1. Log on to the server as a member of the local Administrators group.
2. Open Windows Explorer and navigate to the shared folder.
3. Right-click the folder, and then click **Properties**.
4. Click the **Sharing** tab, click **Advanced Sharing**, and then click **Permissions**.
5. Ensure that the Hyper-V computer accounts, the SYSTEM account, and all Hyper-V administrators have full control permissions.

6. Click **OK** twice.
7. Click the **Security** tab.
8. Ensure that the Hyper-V computer accounts, the SYSTEM account, and all Hyper-V administrators have full control permissions.

3.2. Create a new virtual machine

You create a virtual machine by using Hyper-V Manager. When you are prompted for the virtual machine location, enter the name of the client access point that is configured in the failover cluster for Scale-Out File Server.

To create a virtual machine

1. Log on to the server running Hyper-V as a member of the local Administrators group.
2. Open Hyper-V Manager. Click **Start**, and then click **Hyper-V Manager**.
3. Right-click the server running Hyper-V name, point to **New**, and then click **Virtual Machine**.
4. On the **Before You Begin** page, click **Next**.
5. On the **Specify Name and Location** page, in the **Name** box, type a name for the virtual machine.
6. Select the **Store the virtual machine in a different location** check box. In the **Location** box, type the client access point that is configured in the failover cluster for Scale-Out File Server, and then click **Next**.
7. On the **Assign Memory** page, type the desired amount of memory in the **Startup memory** box, and then click **Next**.
8. On the **Configure Networking** page, in the **Connection** box, choose the appropriate network, and then click **Next**.
9. On the **Connect Virtual Hard Disk** page, create a virtual hard disk and set the location to the client access point that is configured in the failover cluster for Scale-Out File Server, and then click **Next**.
10. On the **Completing the New Virtual Machine Wizard** page, click **Finish**.

- Step 2: Configure Scale-Out File Server
- Step 4: Configure Microsoft SQL Server to Use Scale-Out File Server
- Deploy Scale-Out File Server
- Scale-Out File Server for Application Data Overview

Step 4: Configure Microsoft SQL Server to Use Scale-Out File Server

SQL Server is one of two Microsoft applications that are supported when using File Server for scale-out application data storage. SQL Server 2008 R2 and SQL Server 2012 are supported in this scenario. SQL Server 2008 R2 is supported in a stand-alone configuration, and SQL Server 2012 adds support for clustered servers.

Task	Description
4.1. Verify permissions	Ensure that the permissions on the continuously available file share are configured correctly to host the database files.
4.2. Create the database files	Create the database files by using SQL Server Management Studio or by using a query.

4.1. Verify permissions

You should ensure that the proper permissions are granted on the continuously available file share before you create SQL Server database files.

To verify permissions

1. Log on to the file server as a member of the local Administrators group.
2. Open Windows Explorer and navigate to the scale-out file share.
3. Right-click the folder, and then click **Properties**.
4. Click the **Sharing** tab, click **Advanced Sharing**, and then click **Permissions**.
5. Ensure that the SQL Server service account has full-control permissions.
6. Click **OK** twice.
7. Click the **Security** tab.
8. Ensure that the SQL Server service account has full-control permissions.

4.2. Create the database files

When creating the database files, you can store the database files in a scale-out file share by using SQL Server Management Studio or by using a query. In SQL Server 2012, you can choose to store all database files in a scale-out file share during installation.

Network Performance and Availability

This topic describes how Server Message Block (SMB) Multichannel provides a network performance and availability experience in Server Availability.

Scenario description

In Windows Server 2012, the SMB Multichannel feature provides multiple connections within a single SMB session to enhance the network performance and availability experience for Server Availability. SMB Multichannel provides the following advantages:

- **Failover** Uses a different network adapter if a network adapter fails in a computer.
- **Throughput** Aggregates bandwidth across multiple network adapters, and uses multiple processors to process network interruptions on network adapters that support Receive Side Scaling.
- **Configuration** Automatically detects and uses multiple network paths.

Practical applications

Some practical applications of the network performance and availability experience include:

- **SQL over SMB** Install SQL database files on an SMB network share. For more information about SQL over SMB, see Install SQL Server with SMB fileshare as a storage option.
- **Hyper-V over SMB** Enable virtual machines to reside on an SMB network shares, giving you the power to design new flexible storage solutions for your virtual or cloud infrastructure.

Features included in this experience

The following table lists the features that are part of this scenario and describes how they support it.

Role/feature	How it supports this scenario
Server Message Block overview	SMB Multichannel is a new feature in the SMB version 3.0 protocol.

Role/feature	How it supports this scenario
NIC Teaming Overview	Load balancing and failover (also known as network adapter teaming), allows multiple network adapters on a computer to be placed into a team.

Hardware requirements

SMB Multichannel requires at least one of the following configurations:

- Multiple network adapters
- Network adapters that support Receive Side Scaling
- Network adapters that support Remote Direct Memory Access (RDMA)

The following are a few sample network configurations that can be used for SMB Multichannel:

- **Dual 1 gigabit Ethernet network adapters** Each computer running Windows Server 2012 is configured with a dual 1 gigabit Ethernet network adapter.
- **Dual 1 gigabit Ethernet network adapters configured in a team** Each computer is configured with two 1 gigabit Ethernet network adapters that are configured in a load balancing and failover environment, also known as a network adapter team.
- **Single 10 gigabit Ethernet network adapters** Each computer running Windows Server 2012 is configured with a 10 gigabit Ethernet network adapter that support Receive Side Scaling.
- **Dual 10 gigabit Ethernet network adapters** Each computer is configured with a dual 10 gigabit Ethernet network adapter.
- **Dual Infiniband network adapters** Each computer is configured with dual Infiniband network adapters that support RDMA.

Software requirements

SMB Multichannel is enabled by default on computers running Windows Server 2012.

Deploy Hyper-V over SMB

SMB 3.0 file shares can be used as shared storage for Hyper-V in Windows Server 2012 R2 and Windows Server 2012. With this capability, Hyper-V can store virtual machine files, which includes configuration, virtual hard disk (VHD) files, and snapshots, on SMB file shares. Listed below are the main advantages of storing application data for Hyper-V on SMB file shares:

- **Ease of provisioning and management.** You can manage file shares instead of storage fabric and logical unit numbers (LUNs).

- **Increased flexibility.** You can dynamically migrate virtual machines or databases in the data center.
- **Ability to take advantage of existing investment in a converged network.** You can use your existing converged network with no specialized storage networking hardware.
- **Reduced capital expenditures.** Capital expenses (acquisition costs) are reduced.
- **Reduced operating expenditures.** You can reduce operating costs because there is no need for specialized storage expertise.

Note
Some Hyper-V features in Windows Server 2012 R2 and Windows Server 2012 now rely on using SMB file shares, such as some types of live migration.

In this guide

- Prerequisites
- Step 1: Configuring file server clusters
- Step 2: Install Hyper-V
- Step 3: Create an SMB file share
- Step 4: Create a virtual machine and virtual hard disk file on the file share
- Step 5: Migrate virtual machine storage to an SMB file share
- Step 6: Initiate a live migration of a virtual machine to another cluster node
- Step 7: Move virtual machines to another Hyper-V host and migrate virtual machine storage
- Troubleshooting

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

Prerequisites

Using Hyper-V with SMB has the following requirements:

- One or more computers running Windows Server 2012 R2 or Windows Server 2012 with the Hyper-V role installed. You can also use non-Microsoft file servers that implement the SMB 3.0 protocol.
- One or more computers running Windows Server 2012 R2 or Windows Server 2012 with the File and Storage Services role installed.
- A common Active Directory infrastructure. The servers running Active Directory Domain Services (AD DS) do not need to run Windows Server 2012 R2 or Windows Server 2012.

The three most common file server configurations for Hyper-V over SMB are a single-node file server, a dual-node file server, and a multi-node file server, as shown in the following figure.

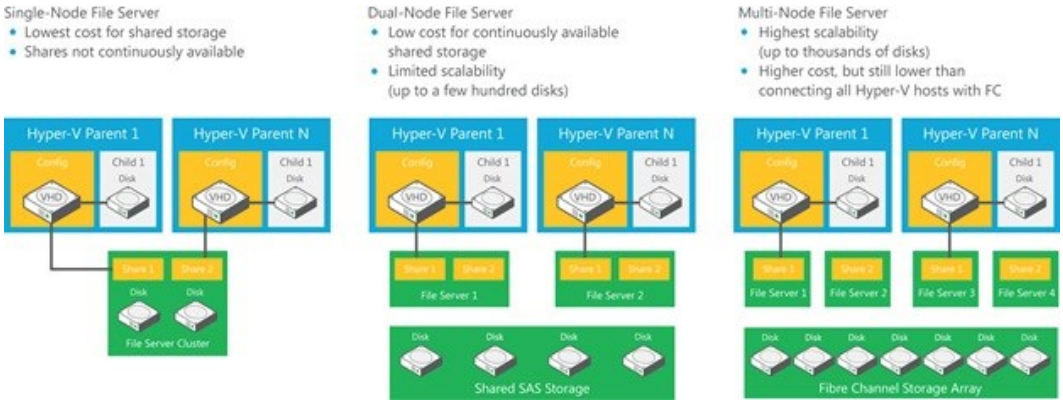

Figure 1 Common configurations for Hyper-V over SMB2

The two supported Hyper-V configurations for Hyper-V over SMB are:

- Standalone Hyper-V servers (not a high availability solution)
- Hyper-V servers configured in a failover cluster

Note

The Hyper-V host must have Windows Server 2012 R2 or Windows Server 2012 installed.

Considerations when using Hyper-V with SMB

- An Active Directory infrastructure is required, so you can grant permissions to the computer account of the Hyper-V hosts.
- The file server must have Windows Server 2012 R2 or Windows Server 2012 installed, so the new SMB 3.0 protocol is available. You can also use non-Microsoft file servers that implement the SMB 3.0 protocol. Hyper-V does not block older versions of SMB, however, the Hyper-V Best Practice Analyzer issues an alert when an older version of SMB is detected.
- Loopback configurations (where the computer that is running Hyper-V is used as the file server for virtual machine storage) are not supported.
- You must have separate failover clusters for Hyper-V and for the file server.

Step 1: Configuring file server clusters

To deploy Hyper-V over SMB, use one of the following procedures for your file server configuration. All servers in your file server configuration must have Windows Server 2012 R2 or Windows Server 2012 installed.

To configure a standalone file server

1. Log on to the server as a member of the local Administrators group.
2. Server Manager will start automatically. If it does not automatically start, click **Start**, type

servermanager.exe, and then click **Server Manager**.

3. In the **QUICK START** section, click **Add roles and features**.
4. On the **Select installation type** page, click **Role-based or feature-based installation**, and then click **Next**.
5. On the **Select destination server** page, select the appropriate server, and then click **Next**. The local server is selected by default.
6. On the **Select server roles** page, click **File and Storage Services**, and then click **Next**.
7. On the **Confirm installation selections** page, click **Install**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

To add the File and Storage Services role, type:

```
Install-WindowsFeature File-Services, FS-FileServer
```

If you are using SMB Multichannel, ensure there are two network adapters with identical type and speed available. To view the list of network adapters, type:

```
Get-NetAdapter

Get-SmbServerNetworkInterface
```

To configure a clustered file server

1. With Windows Server 2012 R2 or Windows Server 2012 installed on two servers, add the File and Storage Services role and the Failover Clustering feature on each server by typing:

   ```
   Install-WindowsFeature File-Services, FS-FileServer,
   Failover-Clustering

   Install-WindowsFeature RSAT-Clustering -IncludeAllSubFeature
   ```

2. If you are using SMB Multichannel, ensure there are two network adapters with identical type and speed available and that they are configured on different subnets. To view the list of network adapters, type:

   ```
   Get-NetAdapter

   Get-SmbServerNetworkInterface
   ```

3. To create a failover cluster using the two servers, type:

   ```
   New-Cluster –Name ClusterName -Node FileServer1, FileServer2
   ```

4. To create a file server cluster to host continuously available SMB file shares, where `FST` is the name of the file server cluster and `Cluster Disk 1` is the storage, type:

   ```
   Add-ClusterFileServerRole -Name FST -Storage "Cluster Disk 1"
   –StaticAddress 192.168.101.22/24, 192.168.102.22/24
   ```

The above example assumes you are using two networks with addresses, 192.168.101.22/24 and 192.168.102.22/24, for SMB network traffic. Two networks are recommended for network fault tolerance.

To configure a failover cluster with a scale-out file server

1. Follow steps 1-3 in the previous procedure, To configure a clustered file server.
2. To create a scale-out file server on the failover cluster to host continuously available SMB file shares, where `FSO` is the name of the scale-out file server cluster and `Cluster Disk 2` is the name of the storage, type:

```
Add-ClusterSharedVolume "Cluster Disk 2"
Add-ClusterScaleOutFileServerRole -Name FSO
```

Step 2: Install Hyper-V

To continue deploying Hyper-V over SMB, install the Hyper-V role on a separate server.

To install the Hyper-V role

1. To install the Hyper-V role on a separate server, follow steps 1-5 from To configure a standalone file server.
2. On the **Select server roles** page, click **Hyper-V**, and then click **Next**.
3. On the **Confirm installation selections** page, click **Install**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

To install the Hyper-V role and Hyper-V Windows PowerShell cmdlets and tools, type:

```
Install-WindowsFeature Hyper-V, Hyper-V-PowerShell, Hyper-V-Tools
```

If you are using SMB Multichannel, ensure there are two network adapters with identical type and speed available, and they are not connected to the virtual switch. To view the list of network adapters, type:

```
Get-NetAdapter

Get-SmbClientNetworkInterface
```

Step 3: Create an SMB file share

The folder used by Hyper-V to store virtual machine data requires specific permissions to access the SMB file share. You need to make sure that the Hyper-V computer accounts, the SYSTEM account, and all Hyper-V administrators have full control permissions.

To create an SMB file share by using Server Manager

1. Log on to the server as a member of the local Administrators group.
2. Server Manager will start automatically. If it does not automatically start, click **Start**, type **servermanager.exe**, and then click **Server Manager**.
3. On the left, click **File and Storage Services**.
4. Click **Tasks**, and then click **New Share** to open the **New Share Wizard**.
5. On the **Select Profile** page, select **SMB Share – Applications**, and click **Next**.
6. On the **Share Location** page, select a server and a volume, and click **Next**.
7. On the **Share Name** page, specify a name for the new share, and click **Next**.
8. On the **Permissions** page, click **Customize Permissions**.
9. Click **Add**, click **Select a Principal**, and then click **Object Types**.
10. In **Object Types**, click to select **Computers**, and click **OK**.
11. Enter the name of the computer, and click **OK**.
12. In **Permissions Entry**, select **Full Control**, and click **OK**.
13. Repeat the previous three steps for the second Hyper-V server. Click OK when finished.
14. On the **Permissions** page, click **Next**.
15. Click **Create** to create the SMB file share.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

For a standalone file server or a clustered file server, type the following to configure an SMB file share (where `HV1` and `HV2` are servers running Hyper-V, `HVC` is the Hyper-V cluster account, and `HVadmin` is the Hyper-V administrator account):

```
# Create folder

MD X:\VMS

# Create file share

New-SmbShare -Name VMS1 -Path X:\VMS -FullAccess Domain\HVAdmin, Domain\HV1$,
Domain\HV2$, Domain\HVC$

# Set NTFS permissions from the file share permissions

Set-SmbPathAcl -Name VMS1
```

For a scale-out file server cluster, type the following to configure an SMB file share (where `HV1` and `HV2` are servers running Hyper-V and `HVadmin` is the Hyper-V administrator account):

```
# Create folder

MD X:\VMS

# Create file share
```

```
New-SmbShare -Name VMS1 -Path X:\VMS -FullAccess Domain\HVAdmin, Domain\HV1$,
Domain\HV2$, Domain\HVC$
apply permissions
# Set NTFS permissions from the file share permissions
Set-SmbPathAcl -Name VMS1
```

Step 4: Create a virtual machine and virtual hard disk file on the file share

To create a virtual hard disk (VHD) and virtual machine on an SMB file share, use Hyper-V Manager or Hyper-V Windows PowerShell cmdlets. You will also need to specify a Universal Naming Convention (UNC) path (for example, \\servername\sharename).

To create a virtual machine

1. Open Hyper-V Manager. From the Server Manager Tools menu, click **Hyper-V Manager**.
2. From the navigation pane of Hyper-V Manager, select the computer running Hyper-V.
3. From the Actions pane, click **New** and then click **Virtual Machine**.
4. The New Virtual Machine wizard opens. Click **Next**.
5. On the **Specify Name and Location** page, type an appropriate name and location (using a UNC path). To configure Hyper-V over SMB, you must use a UNC path.
6. On the **Assign Memory** page, specify enough memory to start the guest operating system.
7. On the **Configure Networking** page, connect the virtual machine to the switch you created when you installed Hyper-V.
8. On the **Connect Virtual Hard Disk** and **Installation Options** pages, choose **Create a virtual hard disk**. Click **Next**, and then click the option that describes the type of media you will use. For example, to use an .iso file, click **Install an operating system from a boot CD/DVD** and then specify the path to the .iso file.
9. On the Summary page, verify your selections and then click **Finish**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

For a file server named `FS1` and a file share named `VMS`, to create a virtual machine named `VM1`, type:

```
New-VHD -Path \\FS1\VMS\VM1.VHDX -VHDType Dynamic -SizeBytes 127GB
New-VM -Name VM1 -Path \\FS1\VMS -Memory 1GB -VHDPath \\FS1\VMS\VM1.VHDX
```

Step 5: Migrate virtual machine storage to an SMB file share

You can migrate virtual machine storage from both direct-attached storage (DAS) to an SMB file share and from a SMB file share to another SMB file share.

To migrate virtual machine storage from local storage to an SMB file share

1. To confirm that there is a virtual machine using local storage, type:

   ```
   Get-VM VM1 | FT Name, Path, State
   Get-VMHardDiskDrive VM1 | FT VMName, Path
   ```

   To migrate virtual machine storage from an SMB file share to another SMB file share, specify the SMB file share in this step.
2. Start a prolonged process, such as running a file copy workload, inside of the guest operating system.
3. To migrate the virtual machine storage to an SMB file share, type:

   ```
   Move-VMStorage –VMName VM1 –DestinationStoragePath \\FST\VMS
   ```
4. To confirm that a virtual machine is using an SMB file share and the workload is not interrupted, type:

   ```
   Get-VM VM1 | FT Name, Path, State
   Get-VMHardDiskDrive VM1 | FT VMName, Path
   ```

Step 6: Initiate a live migration of a virtual machine to another cluster node

You can transparently move running virtual machines from one cluster node to another node in the same cluster without a dropped network connection or perceived downtime.

To initiate a live migration of a virtual machine to another cluster node

1. To confirm that a virtual machine is running in a cluster node and is using an SMB file share, type:

   ```
   Get-VM VM1 | FT Name, Path, State
   Get-VMHardDiskDrive VM1 | FT VMName, Path
   Get-ClusterGroup VM1 | FT Name, OwnerNode, State
   ```
2. Start a prolonged process, such as running a file copy workload, inside of the guest operating system.
3. To perform a live migration of a virtual machine to another cluster node, type:

   ```
   Move-ClusterVirtualMachineRole -Name VM1 -Node HV2 –
   ```

```
VmMigrationType Live
```

4. To confirm that the virtual machine moved to another cluster node and the workload is not interrupted, type:

```
Get-ClusterGroup VM1 | FT Name, OwnerNode, State
```

Step 7: Move virtual machines to another Hyper-V host and migrate virtual machine storage

To move running virtual machines from one cluster node to another node in the same cluster and migrate virtual machine storage, use one of the following procedures:

To move a virtual machine to another Hyper-V host

1. To confirm that a virtual machine is running on the Hyper-V host, type:

```
Get-VM VM1 | FT Name, Path, State
```

2. Start a prolonged process, such as running a file copy workload, inside of the guest operating system.
3. To perform a live migration of a virtual machine to another Hyper-V host, type:

```
Move-VM –Name VM1 –DestinationHost HV2
```

4. To confirm that the virtual machine moved to another Hyper-V host and the workload is not interrupted, type:

```
Get-VM VM1 | FT Name, Path, State
```

To move a virtual machine with direct-attached storage and migrate its virtual machine storage to an SMB file share

1. To confirm that a virtual machine with local storage is running on the Hyper-V host, type:

```
Get-VM VM1 | FT Name, Path, State

Get-VMHardDiskDrive VM1 | FT VMName, Path
```

   To migrate virtual machine storage from an SMB file share to another SMB file share, specify the SMB file share in this step.

2. Start a prolonged process, such as running a file copy workload, inside of the guest operating system.
3. To move the virtual machine to another Hyper-V host and the storage to an SMB file share, type:

```
Move-VM –Name VM1 -DestinationHost HV2 –
DestinationStoragePath \\FST\VMS
```

4. To confirm that the virtual machine moved to another Hyper-V host using the SMB file share, and the workload is not interrupted, type:

```
Get-VM VM1 | FT Name, Path, State
Get-VMHardDiskDrive VM1 | FT VMName, Path
```

Troubleshooting

This section covers some common issues that you might encounter when using Hyper-V over SMB.

Check and fix issues with permissions

You may experience issues with permissions that are related to accessing an SMB file share or the NTFS folder on which the share was created. To check permissions on an SMB file share (where `VMS1` is the share and `X:\VMS` is the NTFS folder), type the following:

```
Get-SmbShareAccess -Name VMS1 -Path X:\VMS
```

If you determine that a specific computer account is missing from permissions, you can add the account to both the file share and the folder to fix the issue. To fix the permissions, type the following:

```
Grant-SmbShareAccess –Name VMS1 –AccountName Domain\HV3$ -AccessRight Full
Set-SmbPathAcl –Name VMS1
```

Using constrained delegation

When using Hyper-V Manager from a computer running Windows Server 2012 R2 or Windows Server 2012 to manage virtual machines on another computer running Windows Server 2012 R2 or Windows Server 2012, you may experience an error that says access to an SMB file share is denied. Typically, this is because you need delegation rights to use your credentials to access the remote share on another computer. This is a security feature that prevents a user from gaining access to a computer in your network for the purpose of performing actions on other computers in your network. To address this issue, you have two choices:

Option 1: Use Remote Desktop. Use Remote Desktop to access the computer and run Hyper-V Manager directly on that computer.

Option 2: Configure constrained delegation. You can change the properties of the computer account in Active Directory Users and Computers to allow delegation. When enabled, constrained delegation gives you the ability to use a specific SMB remote file share without requiring you to perform an action on any computer. Constrained delegation tells Active Directory Users and Computers that between two computers, (in this case, the Hyper-V server and the SMB file server), and for specific services, (in this case, SMB), it is allowed to re-issue access to the resources.

To configure constrained delegation, for each server running Hyper-V, perform one of the following procedures.

Note

In Windows Server 2012 R2, you can perform this procedure using a new set of Windows PowerShell SMB cmdlets that simplifies the configuration of constrained delegation.

To configure constrained delegation

1. In Active Directory Users and Computers, click to open **Properties** for the computer account, and then click to open the **Delegation** tab.
2. Select both **Trust this computer for delegation to the specified services only** and **Use Kerberos only**.
3. Click **Add**, and provide the name of the SMB file server (or the **Cluster Access Point** for a Scale-Out File Server).
4. Select the **CIFS** service. Note that Common Internet File System (CIFS) is the previous name for SMB.
5. On the SMB file share created for virtual machines, add Full Control permissions for the Hyper-V Administrators.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

Before you perform this procedure using the Windows PowerShell SMB cmdlets, the Active Directory module for Windows PowerShell must be available. To install the Active Directory cmdlets, type:

```
Install-WindowsFeature RSAT-AD-PowerShell
```

To configure constrained delegation (where `FileServer1` and `FileServer2` are the servers running Hyper-V and `HV1` and `HV2` are the SMB clients), type:

```
Enable-SmbDelegation –SmbServer FileServer1 –SmbClient HV1

Enable-SmbDelegation –SmbServer FileServer1 –SmbClient HV2

Enable-SmbDelegation –SmbServer FileServer2 –SmbClient HV1

Enable-SmbDelegation –SmbServer FileServer2 –SmbClient HV2
```

Note

This procedure works only with the resource-based constrained delegation available starting in Windows Server 2012, therefore, the Active Directory forest must be at the Windows Server 2012 functional level.

Protect Data on Remote SMB File Shares using VSS

In Windows Server 2012, a new feature is introduced called VSS for SMB File Shares, which allows VSS-aware backup applications to create a volume shadow copy of VSS-aware server applications that store data on remote SMB 3.0 file shares. This guide provides information on how to perform backups of server applications using this feature, and therefore, protect your data.

In this document

- VSS for SMB File Shares: overview
- Requirements and supported configurations
- Deployment scenarios
- Step 1: Install File Server VSS Agent Service
- Step 2: Add a user to the Backup Operators local group on the file server
- Step 3: Perform a shadow copy

Note

This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

VSS for SMB File Shares: overview

VSS for SMB File Shares is an extension to the existing VSS infrastructure and consists of four parts:

- **File Share Shadow Copy Provider (fssprov.dll)**. This is a new VSS provider on the server running the VSS-aware application. It manages shadow copies on remote Universal Naming Convention (UNC) paths where the application stores its data files, and then relays the shadow copy request to the File Share Shadow Copy Agents. Enhancements to the VSS infrastructure to support the File Share Shadow Copy Provider include updates to the API.
- **File Share Shadow Copy Agent (fssagent.dll)**. This is a new VSS requester on the file server hosting the SMB 3.0 file shares (using an UNC path) that store the application's data files. It manages mappings between file shares and volumes, and also interacts with the file server's VSS infrastructure to perform shadow copies of the volumes that backup the SMB 3.0 file shares (where the VSS-aware applications stores their data).
- **File Server Remote VSS Protocol (MSFSRVP)**. The File Share Shadow Copy Provider and the File Share Shadow Copy Agent use this new RPC-based protocol to coordinate shadow copy requests of data stored on SMB file shares.

Requirements and supported configurations

The requirements for using VSS for SMB File Shares are listed below.

- The application server and file server must be running Windows Server 2012.

- The application server and file server must be joined to the same Active Directory domain.
- The File Server VSS Agent Service role service must be installed on the file server.
- The File Share Shadow Copy agent must run in a security environment that has backup operators or administrator privileges on both the application server and file server.
- The File Share Shadow Copy agent and the application must run in a security environment that has no less than read-only permission on the file share data that will be backed up.

Note
VSS for SMB File Shares also works with third-party Network Attached Storage (NAS) appliances or other similar solutions. These appliances or solutions must support SMB 3.0 and File Server Remote VSS Protocols.

VSS for SMB File Shares supports the following configurations:

- An application server configured as a single server or in a failover cluster.
- A file server configured as a single server or in a failover cluster with continuously available or scale-out file shares.
- File shares with a single DFS Namespaces link target.

VSS for SMB File Shares has the following limitations:

- Unsupported VSS capabilities, such as: hardware transferrable shadow copies, writable shadow copies, VSS fast recovery where a volume can quickly revert to a shadow copy, and client-accessible shadow copies (Shadow Copy of Shared Folders).
- Loopback configurations where an application server accesses its data on SMB file shares that are hosted on the same application server.
- Shadow copies of Hyper-V virtual machines, where the application for which the virtual machine stores its data on SMB file shares is not supported.
- Data on mounted drives that are below the root of the file share are not included in the shadow copy.
- Shadow copies of file shares that do not support failover clustering.

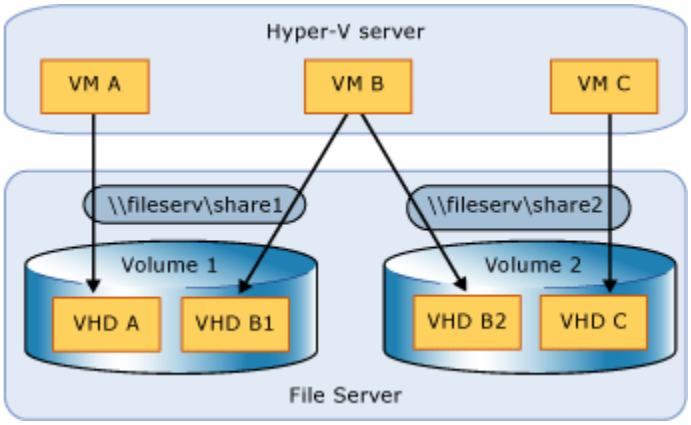
Deployment scenarios

VSS for SMB File Shares is most commonly deployed with Hyper-V, where a server running Hyper-V stores the virtual machine files on remote SMB file share. Some example deployments are described below.

Single server running Hyper-V and single file server

In this scenario, there is a single, non-clustered server running Hyper-V and a single, non-clustered file server. As shown in the diagram below, the file server has two volumes attached to it, with a file share on each volume. The virtual machine files for `VM A` are stored on `\\fileserv\share1`, which is backed by `Volume 1`. For `VM B`, some of the virtual machine files are stored on `\\fileserv\share1`, and some are stored on `\\fileserv\share2`, which is backed by `Volume 2`. The virtual machine files for `VM C` are stored on `\\fileserv\share2`.

Diagram of a single server running Hyper-V and a single file server



When a backup operator performs a shadow copy of `VM A`, the Hyper-V VSS writer adds `\\fileserv\share1` to the shadow copy set. When ready, the File Share Shadow Copy Provider sends the shadow copy request to `\\fileserv`. On the file server, the File Share Shadow Copy Agent invokes the local VSS service to perform a shadow copy of `Volume 1`. `Volume 2` is not part of the shadow copy set since only `\\fileserv\share1` was reported by the VSS writer. When the shadow copy sequence is complete, a shadow copy share `\\fileserv\share1@{GUID}` is available for the backup application to move the backup data. When the backup is complete, the backup application releases the shadow copy set, and the associated shadow copies and shadow copy shares are removed.

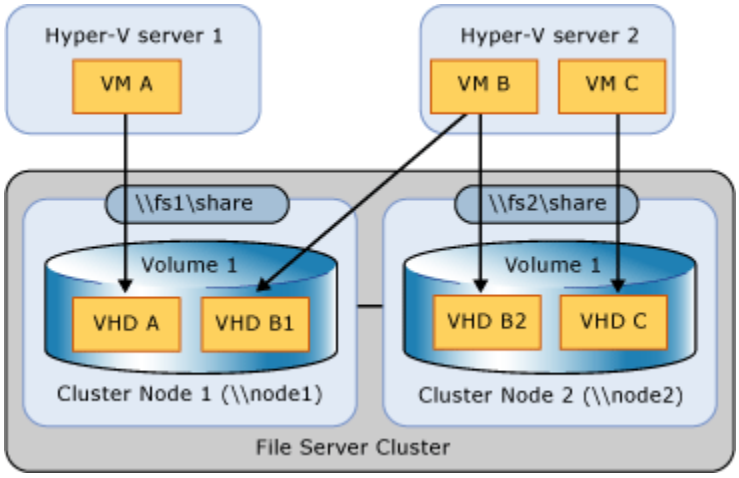
If the backup operator performs a shadow copy of `VM B`, the Hyper-V VSS writer reports both `\\fileserv\share1` and `\\fileserv\share2` in the shadow copy set. On the file server, this results in a shadow copy of both `Volume 1` and `Volume 2`, and two shadow copy shares `\\fileserv\share1@{GUID}` and `\\fileserv\share2@{GUID}` are created.

If the backup operator performs a shadow copy of `VM A` and `VM B`, the Hyper-V VSS writer reports both `\\fileserv\share1` and `\\fileserv\share2` in the shadow copy set. On the file server, a shadow copy of both volumes is generated and two shadow copy shares are created.

Two servers running Hyper-V and a file server cluster

In this scenario, there are two servers running Hyper-V and a file server cluster. As shown in the diagram below, the file server cluster has two cluster nodes, `node1` and `node2`. The file server cluster, `\\fs1`, is currently online on `node1`, with a single share, `\\fs1\share`, on `Volume 1`. To use both cluster nodes, a second file server cluster, `\\fs2`, is configured and is currently online on `node2`, with a single share, `\\fs2\share`, on `Volume 2`.

Diagram of two servers running Hyper-V and a file server cluster



When the backup operator performs a shadow copy of `VM A`, the Hyper-V VSS writer reports `\\fs1\share` in the shadow copy set. When ready, the File Share Shadow Copy Provider sends a shadow copy request to `\\fs1`. As part of the exchange between the File Share Shadow Copy Provider and the File Share Shadow Copy Agent, the agent notifies the provider of the physical computer name, `node1`, which is actually performing the shadow copy.

On `node1`, the File Share Shadow Copy Agent calls the local VSS service to perform a shadow copy of the volume that backs the file share. When the shadow copy sequence is complete, a shadow copy share `\\node1\share@{GUID}` is available for the backup application to stream the backup data. Note the shadow copy share, `\\node1\share@{GUID}`, is targeted to the cluster node, `node1`, and not the virtual computer name, `\\fs1`.

Once the backup is complete, the backup application releases the shadow copy set and the associated shadow copies and shadow copy shares are removed. If the file server cluster moves to, or fails over to, `node2` before the backup sequence is complete, the shadow copy share and the shadow copy become invalid. If the file server cluster moves back to `node1`, the shadow copy and the corresponding shadow copy share will become valid again.

Step 1: Install File Server VSS Agent Service

Use one of the following procedures to install File Server VSS Agent Service.

To install File Server VSS Agent Service using Server Manager

1. From the Add Roles and Features Wizard, under Server Roles, select **File and Storage Services** if it has not already been installed.
2. Under **File and iSCSI Services**, select **File Server** and **File Server VSS Agent Service**.
3. On the **Select Features** page, click **Next**.
4. On the **Confirmation** page, verify that **File Server** and **File Server VSS Agent Service**

are listed, and then click **Install**.

The next part of Step 1 is where you include the Windows PowerShell equivalent to the GUI procedure. Delete this part if there is no PowerShell equivalent.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

Provide the Windows PowerShell code for the procedure. For example:

```
PS C:\> Import-Module ServerManager

PS C:\> Add-WindowsFeature -name File-Services,FS-VSS-Agent
```

Step 2: Add a user to the Backup Operators local group on the file server

The user who is performing the shadow copy must have the backup administrative privileges on the remote file servers that are included in the shadow copy set. Usually, this is accomplished by adding the user to the Backup Operators group on the file servers. Use one of the following procedures to do this.

To add a user to the Backup Operators local group on the file server using Server Manager

1. From the dashboard in Server Manager, click **Tools**, and then click **Computer Management**.
2. In Computer Management, expand **Local Users and Groups**, and then expand **Groups**.
3. Double-click **Backup Operators**.
4. On the **Backup Operators Properties** page, click **Add**.
5. Type of the name of the user you want to add to the Backup Operators group, and click **OK**.

Windows PowerShell equivalent commands

The following Windows PowerShell cmdlet or cmdlets perform the same function as the preceding procedure. Enter each cmdlet on a single line, even though they may appear word-wrapped across several lines here because of formatting constraints.

In the example below, modify the user account and the name of the file server to apply to your environment.

```
$objUser = [ADSI]("WinNT://domain/user")

$objGroup = [ADSI]("WinNT://fileserv/Backup Operators")

$objGroup.PSBase.Invoke("Add",$objUser.PSBase.Path)
```

Step 3: Perform a shadow copy

You must have a VSS-aware backup application that supports VSS for SMB File Shares to perform a shadow copy of an application's data that is stored on a remote file share.

Note
Windows Server Backup in Windows Server 2012 does not support VSS for SMB File Shares.

This section contains examples of performing a shadow copy of a virtual machine that has its data files stored on an SMB file share using DiskShadow.exe (a tool that exposes the functionality offered by VSS), and Microsoft System Center Data Protection Manager 2012 Service Pack 1. For information on how to backup and protect data using Microsoft System Center Data Protection Manager 2012 SP1, see Managing Hyper-V computers.

To perform a shadow copy of virtual machine on the Hyper-V host (HV1) using DiskShadow

1. Start Windows PowerShell. Right-click the PowerShell icon on the taskbar, and select **Run as Administrator**.

   Run the following Windows PowerShell command:

   ```
   PS C:\Users\administrator> DISKSHADOW
   ```

2. Type the following:

   ```
   DISKSHADOW> Writer Verify {66841cd4-6ded-4f4b-8f17-fd23f8ddc3de}
   DISKSHADOW> Set Context Persistent
   DISKSHADOW> Set MetaData vm1backup.cab
   DISKSHADOW> Begin Backup
   DISKSHADOW> Add Volume \\smbsofs\vm\vm1
   DISKSHADOW> Create
   ```

   The following output appears:

   ```
   Alias VSS_SHADOW_1 for shadow ID {7b53b887-76e5-4db8-821d-
   6828e4cbe044} set as environment variable.
   Alias VSS_SHADOW_SET for shadow set ID {2bef895d-5d3f-4799-8368-
   f4bfc684e95b} set as environment variable.
   Querying all shadow copies with the shadow copy set ID
   {2bef895d-5d3f-4799-8368-f4bfc684e95b}
   * Shadow copy ID = {7b53b887-76e5-4db8-821d-6828e4cbe044}
   %VSS_SHADOW_1%
   ```

```
- Shadow copy set: {2bef895d-5d3f-4799-8368-f4bfc684e95b}
%VSS_SHADOW_SET%
- Original count of shadow copies = 1
- Original volume name: \\SMBSOFS\VM\ [volume not on this
machine]
- Creation time: 5/30/2012 5:35:52 PM
- Shadow copy device name: \\FSF-260403-09\VM@{F1C5E17A-4168-
4611-9CD4-8366F9F935C3}
- Originating machine: FSF-260403-09
- Service machine: CONTOSO.SMBTEST.stbtest.microsoft.com
- Not exposed
- Provider ID: {89300202-3cec-4981-9171-19f59559e0f2}
- Attributes: No_Auto_Release Persistent FileShare
Number of shadow copies listed: 1
```

Type the following to end the backup operation:

```
DISKSHADOW> End Backup
```

In this example, the following command parameters are used:

Writer Verify. This parameter specifies that the backup or restore operation must fail if the writer or the component is not included. For more information, see Invoking diskshadow to back up a Virtual Machine from a Hyper-V Host.

Set Context Persistent. This parameter sets the shadow copy to be persistent, which means that the user or the application controls when to delete the shadow copy.

Set MetaData. This parameter stores the metadata information for the shadow copy (which is needed for restore) in the specified file.

Add Volume. This parameter adds the UNC path to the shadow copy set. You can specify multiple paths by repeating the Add Volume parameter.

Create. This parameter initiates the shadow copy. When the shadow copy is created, DiskShadow generates the properties of the shadow copy. The shadow Copy device name is the path for the shadow copy data, which can be copied to the backup store using XCOPY or other tools.

Note

During the backup session, you can see the virtual machine status reporting **Backing up..** in Hyper-V Manager. The backup session starts with the Create parameter, and then ends with the End Backup command in the DiskShadow sequence above.

To copy the backup data to an alternate location

After the shadow copy is complete, you can view the shadow copy share (which is the shadow copy device name from above), and then copy the data you want to back up to an alternate location.

1. Start Windows PowerShell. Right-click the PowerShell icon on the taskbar, and select **Run as Administrator**.

   Run the following Windows PowerShell command:

```
PS C:\Users\administrator> Get-ChildItem -Recurse -Path "\\FSF-260403-09\VM@{F1C5E17A-4168-4611-9CD4-8366F9F935C3}"

Directory: \\FSF-260403-09\VM@{F1C5E17A-4168-4611-9CD4-8366F9F935C3}

Mode LastWriteTime Length Name

---- ------------- ------ ----

d---- vm1

Directory: \\FSF-260403-09\VM@{F1C5E17A-4168-4611-9CD4-8366F9F935C3}\vm1

Mode LastWriteTime Length Name

---- ------------- ------ ----

d---- vm1

-a--- vm1.vhd

Directory: \\FSF-260403-09\VM@{F1C5E17A-4168-4611-9CD4-8366F9F935C3}\vm1\vm1

Mode LastWriteTime Length Name

---- ------------- ------ ----

d---- Virtual Machines

Directory: \\FSF-260403-09\VM@{F1C5E17A-4168-4611-9CD4-8366F9F935C3}\vm1\vm1\Virtual Machines

Mode LastWriteTime Length Name

---- ------------- ------ ----

d---- 87B27972-46C2-406B-87A4-C3FFA1FB6822

-a--- 28800 87B27972-46C2-406B-87A4-C3FFA1FB6822.xml

Directory: \\FSF-260403-09\VM@{F1C5E17A-4168-4611-9CD4-8366F9F935C3}\vm1\vm1\Virtual

Machines\87B27972-46C2-406B-87A4-C3FFA1FB6822

Mode LastWriteTime Length Name

---- ------------- ------ ----

-a--- 2147602688 87B27972-46C2-406B-87A4-C3FFA1FB6822.bin
```

```
-a--- 20971520 87B27972-46C2-406B-87A4-C3FFA1FB6822.vsv
```

2.

To delete the shadow copy

When the backup data is copied, you can delete the shadow copy.

1. Start Windows PowerShell. Right-click the PowerShell icon on the taskbar, and select **Run as Administrator**.

   Run the following Windows PowerShell command:

   ```
   PS C:\Users\administrator> DISKSHADOW
   ```

2. Type the following:

   ```
   DISKSHADOW> Delete Shadows Volume \\smbsofs\vm
   Deleting shadow copy {7b53b887-76e5-4db8-821d-6828e4cbe044} on
   volume \\SMBSOFS\VM\ from provider {89300202-3cec-4981-91
   71-19f59559e0f2} [Attributes: 0x04400009]...
   Number of shadow copies deleted: 1
   ```

To restore data from a shadow copy

Start Windows PowerShell. Right-click the PowerShell icon on the taskbar, and select **Run as Administrator**.

Run the following Windows PowerShell command:

```
PS C:\Users\administrator> DISKSHADOW
DISKSHADOW> Set Context Persistent
DISKSHADOW> Load MetaData vm1backup.cab
DISKSHADOW> Begin Restore
DISKSHADOW> //xcopy files from backup store to the original
location
DISKSHADOW> End Restore
```

The Load MetaData parameter loads the metadata information for the shadow copy to restore data from the specified file. After running the Begin Restore parameter, you can copy the virtual machine files from the backup store to the original location (\\smbsofs\vm\vm1). For more information, see this Microsoft TechNet blog.

Install and Deploy Windows Server 2012 R2 and Windows Server 2012

Use the articles in this section to learn how to install and deploy Windows Server 2012 R2 and Windows Server 2012.

Windows Server 2012 R2

- System Requirements and Installation Information for Windows Server 2012 R2
  This document provides information about installing the Windows Server 2012 R2 operating system, including important steps to take prior to installation, supported upgrade paths for the release, and information about installing versions distributed as virtual hard disk (VHD) files.
- **Release Notes: Important Issues in Windows Server 2012 R2**
  These release notes address the most critical issues and information about the Windows Server 2012 R2 operating system.
- Upgrade Options for Windows Server 2012 R2
  This document summarizes key information about the supported upgrade paths from previously licensed retail versions of Windows Server to Windows Server 2012 R2.
- Features Removed or Deprecated in Windows Server 2012 R2
  These features and functionalities in Windows Server 2012 R2 have either been removed from the product in the current release or are planned for potential removal in subsequent releases (“deprecated”).
- Common Management Tasks and Navigation in Windows Server 2012 R2 and Windows Server 2012
  Windows Server 2012 R2 and Windows Server 2012 feature the new Modern user interface. This topic helps you find and open common management tools, create shortcuts to frequently used programs, run programs with elevated privileges, and perform common tasks such signing in and out, restarting, and shutting down computers that are running Windows Server 2012 R2 and Windows Server 2012.

Windows Server 2012

- Installing Windows Server 2012
  This document provides information about installing the Windows Server 2012 operating system, including any known issues that you might need to work around before starting an installation. It also provides information that you can use to troubleshoot problems that may occur during the installation.
- Release Notes: Important Issues in Windows Server 2012
  These release notes address the most critical issues and information about the Windows Server 2012 operating system. For information about by-design changes, new features, and fixes in this release, see documentation and announcements from the specific feature teams.
- Evaluation Versions and Upgrade Options for Windows Server 2012
  This document summarizes key information about evaluation versions of Windows Server

2012, including where to obtain them, the limits on their use, and how to convert them to full retail versions. It also summarizes the supported upgrade paths from previously licensed retail versions of Windows Server to Windows Server 2012.

- Windows Server Installation Options
  This document summarizes the differences between the installation options available for Windows Server 2012, including the features that are installed with each option, the management options available after installation, and how to switch between the installation options during use.
- Server Core and Full Server Integration Overview
  In Windows Server 2012, the Server Core installation option is no longer an irrevocable selection that is made during setup. An administrator now has the flexibility to change to a Server Core installation or a full, GUI-based installation as needed, after operating system installation is finished.
- Configure and Manage Server Core Installations
  This collection of topics provides the information needed to install and deploy Server Core servers; install, manage, and uninstall server roles and features; and manage the server locally or remotely. It also includes a quick reference table of common tasks and the commands for accomplishing them locally on a Server Core server.
- Features Removed or Deprecated in Windows Server 2012
  This is a list of features and functionalities in Windows Server 2012 that have either been removed from the product in the current release or are planned for potential removal in subsequent releases. The list is intended for IT pros who are updating operating systems in a commercial environment.
- Common Management Tasks and Navigation in Windows Server 2012 R2 and Windows Server 2012
  Windows 8 and Windows Server 2012 feature the new Windows user interface. This topic helps you find and open common management tools, create shortcuts to frequently used programs, run programs with elevated user rights, and perform common tasks such as signing in and out, restarting, and shutting down computers that are running Windows Server 2012 and Windows 8.

System Requirements and Installation Information for Windows Server 2012 R2

This topic addresses the information you need to install Windows Server® 2012 R2. The process of moving to Windows Server 2012 R2 might vary greatly depending on which operating system you are starting with and the pathway you take. We use the following terms to distinguish among different actions, any of which could be involved in a new Windows Server 2012 R2 deployment.

- **Installation** is the basic concept of getting the new operating system on your hardware. Specifically, a **clean installation** requires deleting the previous operating system.
- **Upgrade** means moving from your existing operating system to Windows Server 2012 R2, while staying on the same hardware. You can upgrade from an evaluation version of

Windows Server 2012 R2, a current retail version of certain editions of Windows Server 2012 R2 (an action known as “license conversion”), a previous retail version of certain editions of Windows Server, or from a volume-licensed edition of Windows Server 2012 R2. Even while staying on the same hardware, some server roles might require specific steps to ensure a smooth upgrade. For detailed information about upgrading by any of these methods to Windows Server 2012 R2, see upgrade options

- **Migration** means moving from your existing operating system to Windows Server 2012 R2 by transferring to a different set of hardware. Migration, which might vary considerably depending on the server roles you have installed, is discussed in detail at http://technet.microsoft.com/en-us/windowsserver/dn458795.

Clean installation

Before you start a clean installation of Windows Server 2012 R2, you should perform the following steps.

1. Review the system requirements
2. Review preinstallation documentation
3. Obtain the product
4. Perform preinstallation tasks

Review system requirements

The following are estimated system requirements for the Windows Server 2012 R2. If your computer has less than the "minimum" requirements, you will not be able to install this product correctly. Actual requirements will vary based on your system configuration and the applications and features you install.

Important
The highly diverse scope of potential deployments makes it unrealistic to state “recommended” system requirements that would be generally applicable. Consult documentation for each of the server roles you intend to deploy for more details about the resource needs of particular server roles. For the best results, conduct test deployments to determine appropriate system requirements for your particular deployment scenarios.

Processor

Processor performance depends not only on the clock frequency of the processor, but also on the number of processor cores and the size of the processor cache. The following are the processor requirements for this product:

- **Minimum**: 1.4 GHz 64-bit processor

RAM

The following are the estimated RAM requirements for this product:

- **Minimum**: 512 MB

Important

If you create a virtual machine with the minimum supported hardware parameters (1 processor core and 512 MB RAM) and then attempt to install this release on the virtual machine, Setup will fail.

To avoid this, do one of the following:

- Allocate more than 800 MB RAM to the virtual machine you intend to install this release on. Once Setup has completed, you can change the allocation to as little as 512 MB RAM, depending on the actual server configuration.
- Interrupt the boot process of this release on the virtual machine with SHIFT+F10. In the command prompt that opens, use Diskpart.exe to create and format an installation partition. Run **Wpeutil createpagefile /path=C:\pf.sys** (assuming the installation partition you created was C:). Close the command prompt and proceed with Setup.

Disk space requirements

The following are the estimated **minimum** disk space requirements for the system partition.

- **Minimum**: 32 GB

Notes

Be aware that 32 GB should be considered an absolute minimum value for successful installation. This minimum should allow you to install Windows Server 2012 R2 in Server Core mode, with the Web Services (IIS) server role. A server in Server Core mode is about 4 GB smaller than the same server in Server with a GUI mode. For the smallest possible installation footprint, start with a Server Core installation and then completely remove any server roles or features you do not need by using Features on Demand. For more information about Server Core and Minimal Server Interface modes, see Windows Server Installation Options.

The system partition will need extra space for any of the following circumstances:

- If you install the system over a network.
- Computers with more than 16 GB of RAM will require more disk space for paging, hibernation, and dump files.

Other requirements

You also must have the following:

- Gigabit (10/100/1000baseT) Ethernet adapter
- DVD drive (if you intend to install the operating system from DVD media)

The following items are not strictly required, but are necessary for certain features:

- Super VGA (1024 x 768) or higher-resolution monitor
- Keyboard and Microsoft® mouse (or other compatible pointing device)
- Internet access (fees may apply)

Review preinstallation documentation

To ensure that you are aware of any issues that might require workarounds, features that have been removed from the product, and features that have been added to the product, review these topics:

- Features Removed or Deprecated in Windows Server 2012 R2
- Release Notes: Important Issues in Windows Server 2012 R2
- What's New in Windows Server 2012 R2

Obtain the server product

You can obtain evaluation versions of Windows Server 2012 R2 (convertible to retail versions) in ISO or VHD format from the TechNet Evaluation Center.

You can obtain evaluation versions (convertible to retail versions) in ISO or VHD format from the TechNet Evaluation Center. You can also buy retail versions from the Microsoft Store.

Perform preinstallation tasks

Before you install Windows Server 2012 R2, follow the steps in this section to prepare for the installation.

- **Disconnect UPS devices.** If you have an uninterruptible power supply (UPS) connected to your destination computer, disconnect the serial cable before running Setup. Setup automatically attempts to detect devices that are connected to serial ports, and UPS equipment can cause issues with the detection process.
- **Back up your servers.** Your backup should include all data and configuration information that is necessary for the computer to function. It is important to perform a backup of configuration information for servers, especially those that provide network infrastructure, such as Dynamic Host Configuration Protocol (DHCP) servers. When you perform the backup, be sure to include the boot and system partitions and the system state data. Another way to back up configuration information is to create a backup set for Automated System Recovery.
- **Disable your virus protection software.** Virus protection software can interfere with installation. For example, it can make installation much slower by scanning every file that is copied locally to your computer.
- **Provide mass storage drivers.** If your manufacturer has supplied a separate driver file, save the file to a floppy disk, CD, DVD, or Universal Serial Bus (USB) flash drive in either the root directory of the media or the **amd64** folder. To provide the driver during Setup, on the disk selection page, click **Load Driver** (or press F6). You can browse to locate the driver or have Setup search the media.

- **Be aware that Windows Firewall is on by default.** Server applications that must receive unsolicited inbound connections will fail until you create inbound firewall rules to allow them. Check with your application vendor to determine which ports and protocols are necessary for the application to run correctly.

  For more information about Windows Firewall, see http://go.microsoft.com/fwlink/?LinkID=84639.

Evaluation versions of Windows Server 2012

Evaluation versions are 64-bit only and can be installed with the Server Core option or the Server with a GUI option. For more information about these installation options, how to convert between them, and how to use the Minimal Server Interface and Features on Demand, see http://technet.microsoft.com//library/hh831786.

For all editions, you have 10 days to complete online activation, at which point the evaluation period begins and runs for 180 days. During the evaluation period, a notification on the Desktop displays the days remaining the evaluation period (except in Windows Server 2012 Essentials). You can also run **slmgr.vbs /dlv** from an elevated command prompt to see the time remaining.

Limits of evaluation versions

All evaluation versions are fully functional during the evaluation period, although booting to Safe mode is not available. The Windows Server 2012 Standard and Windows Server 2012 Datacenter editions come with the activation key pre-installed. After the 180-day evaluation period elapses, the server warns you in various ways depending on the edition:

Windows Server 2012 Standard; Windows Server 2012 Datacenter:

- The following warning appears on the Desktop: **Windows License is expired**
- When you log on to Windows, you are prompted with the following options:
  - Activate now
  - Ask me later
- The system shuts down every hour.
- The only updates that can be installed are security updates.
- Event ID 100 from source WLMS “The license period for this installation of Windows has expired. The operating system will shut down every hour.” appears in the Application log.

Windows Server 2012 Essentials: you receive warnings on the Desktop and on the dashboard, but the server does not shut down.

Installing versions distributed as VHDs

In addition to the other distribution channels, Windows Server 2012 R2 is also available as a pre-configured virtual hard disk (VHD) file, which you can obtain from the TechNet Evaluation Center (http://technet.microsoft.com/en-us/evalcenter/dn205286.aspx). VHD files are available with Windows Server 2012 R2 pre-configured in either Server Core mode or Server with a GUI mode

(though you can switch modes after installation at will). The resulting virtual machine has the following characteristics:

- English only
- 2 GB RAM
- 1 CPU
- 80 GB hard drive

To use the VHD distribution, you must have a computer running Windows Server 2008 R2, Windows Server 2012, or Windows Server 2012 R2. The Hyper-V server role must be installed.

To install the VHD

1. Download the VHD file.
2. Start Hyper-V Manager. On the **Action** menu, select **Import Virtual Machine**.
3. Navigate to the directory that the virtual machine file was extracted to and select the directory (not the directory where the VHD file is located).
4. Select the **Copy the virtual machine option**.
5. Confirm that the import was successful by checking Hyper-V Manager.
6. Configure the network adapter for the resulting virtual machine: right-click the virtual machine and select **Settings**. In the left pane, click **Network Adapter**. In the menu that appears, select one of the network adapters of the virtualization server, and then click **OK**.
7. Start the virtual machine.

Upgrade Options for Windows Server 2012 R2

This topic includes information about upgrading to Windows Server® 2012 R2 from a variety of previous operating systems using a variety of methods.

The process of moving to Windows Server 2012 R2 might vary greatly depending on which operating system you are starting with and the pathway you take. We use the following terms to distinguish among different actions, any of which could be involved in a new Windows Server 2012 R2 deployment.

- **Installation** is the basic concept of getting the new operating system on your hardware. Specifically, a **clean installation** requires deleting the previous operating system. For information about installing Windows Server 2012 R2, see System Requirements and Installation Information for Windows Server 2012 R2. For information about installing other versions of Windows Server, see Windows Server Installation and Upgrade.
- **Upgrade** means moving from your existing operating system release to a more recent release, while staying on the same hardware. For example, if your server is running Windows Server 2012, you can upgrade it to Windows Server 2012 R2. You can upgrade from an evaluation version of the operating system to a retail version, from an older retail version to a newer version, or, in some cases, from a volume-licensed edition of the operating system to an ordinary retail edition.
- **License conversion** in some operating system releases, you can convert a particular edition of the release to another edition of the same release in a single step with a simple command and the appropriate license key. We call this “license conversion.” For example, if you are running Windows Server 2012 R2 Standard, you can convert it to Windows Server 2012 R2 Datacenter.
- **Migration** means moving from your existing operating system to Windows Server 2012 R2 by transferring to a different set of hardware. Migration, which might vary considerably depending on the server roles you have installed, is discussed in detail at http://technet.microsoft.com/en-us/windowsserver/dn458795.

Depending on your scenario, you might encounter a variety of different upgrade pathways.

Upgrading previous retail versions of Windows Server to Windows Server 2012 R2

The table below briefly summarizes which already licensed (that is, not evaluation) Windows operating systems can be upgraded to which editions of Windows Server 2012 R2.

Note the following general guidelines for supported paths:

- In-place upgrades from 32-bit to 64-bit architectures are not supported. All editions of Windows Server 2012 R2 are 64-bit only.
- In-place upgrades from one language to another are not supported.
- In-place upgrades from one build type (fre to chk, for example) are not supported.

- If the server is a domain controller, see http://technet.microsoft.com/library/hh994618.aspx for important information.
- Upgrades from pre-release versions of Windows Server 2012 R2 are not supported. Perform a clean installation to Windows Server 2012 R2.
- Upgrades that switch from a Server Core installation to the Server with a GUI mode of Windows Server 2012 R2 in one step (and vice versa) are not supported. However, after upgrade is complete, Windows Server 2012 R2 allows you to switch freely between Server Core and Server with a GUI modes. For more information about these installation options, how to convert between them, and how to use the new Minimal Server Interface and Features on Demand, see http://technet.microsoft.com/en-us/library/hh831786.

If you do not see your current version in the left column, upgrading to this release of Windows Server 2012 R2 is not supported.

If you see more than one edition in the right column, upgrade to either edition from the same starting version is supported.

If you are running:	You can upgrade to these editions:
Windows Server 2008 R2 Datacenter with SP1	Windows Server 2012 R2 Datacenter
Windows Server 2008 R2 Enterprise with SP1	Windows Server 2012 R2 Standard or Windows Server 2012 R2 Datacenter
Windows Server 2008 R2 Standard with SP1	Windows Server 2012 R2 Standard or Windows Server 2012 R2 Datacenter
Windows Web Server 2008 R2 with SP1	Windows Server 2012 R2 Standard
Windows Server 2012 Datacenter	Windows Server 2012 R2 Datacenter
Windows Server 2012 Standard	Windows Server 2012 R2 Standard or Windows Server 2012 R2 Datacenter
Hyper-V Server 2012	Hyper-V Server 2012 R2
Windows Storage Server 2012 Standard	Windows Storage Server 2012 R2 Standard
Windows Storage Server 2012 Workgroup	Windows Storage Server 2012 R2 Workgroup

Per-server-role considerations for upgrading

Even in supported upgrade paths from previous retail versions to Windows Server 2012 R2, certain server roles that are already installed might require additional preparation or actions for the role to continue functioning after the upgrade. Consult the specific TechNet Library topics for each server role you intend to install for details of additional steps that might be required.

Converting a current evaluation version to a current retail version

You can convert the evaluation version of Windows Server 2012 R2 Standard to either Windows Server 2012 R2 Standard (retail) or Datacenter (retail). Similarly, you can convert the evaluation version of Windows Server 2012 R2 Datacenter to the retail version.

Before you attempt to convert from evaluation to retail, verify that your server is actually running an evaluation version. To do this, do either of the following:

- From an elevated command prompt, run **slmgr.vbs /dlv**; evaluation versions will include “EVAL” in the output.
- From the **Start** screen, open **Control Panel**. Open **System and Security**, and then **System**. View Windows activation status in the Windows activation area of the System page. Click **View details in Windows activation** for more information about your Windows activation status.

If you have already activated Windows, the Desktop shows the time remaining in the evaluation period.

If the server is running a retail version instead of an evaluation version, see the “Upgrading previous retail versions of Windows Server to Windows Server 2012 R2” section of this topic for instructions to upgrade to Windows Server 2012.

For Windows Server 2012 Essentials: You can convert to the full retail version by entering a retail, volume license, or OEM key in the command slmgr.vbs.

If the server is running an evaluation version of Windows Server 2012 Standard or Windows Server 2012 Datacenter, you can convert it to a retail version as follows:

1. If the server is a domain controller, you cannot convert it to a retail version. In this case, install an additional domain controller on a server that runs a retail version and remove AD DS from the domain controller that runs on the evaluation version. For more information, see http://technet.microsoft.com/en-us/library/hh994618.aspx.
2. Read the license terms.
3. From an elevated command prompt, determine the current edition name with the command **DISM /online /Get-CurrentEdition**. Make note of the edition ID, an abbreviated form of the edition name. Then run **DISM /online /Set-Edition:<edition ID> /ProductKey:XXXXX-XXXXX-XXXXX-XXXXX-XXXXX /AcceptEula**, providing the edition ID and a retail product key. The server will restart twice.

For the evaluation version of Windows Server 2012 Standard, you can also convert to the retail version of Windows Server 2012 Datacenter in one step using this same command and the appropriate product key.

Tip

For more information about Dism.exe, see http://go.microsoft.com/fwlink/?LinkId=192466.

Converting a current retail version to a different current retail version

At any time after installing Windows Server 2012, you can run Setup to repair the installation (sometimes called “repair in place”) or, in certain cases, to convert to a different edition.

You can run Setup to perform a “repair in place” on any edition of Windows Server 2012; the result will be the same edition you started with.

For Windows Server 2012 Standard, you can convert the system to Windows Server 2012 Datacenter as follows: From an elevated command prompt, determine the current edition name with the command **DISM /online /Get-CurrentEdition**. Make note of the edition ID, an abbreviated form of the edition name. Then run **DISM /online /Set-Edition:<edition ID> /ProductKey:XXXXX-XXXXX-XXXXX-XXXXX-XXXXX /AcceptEula**, providing the edition ID and a retail product key. The server will restart twice.

Converting a current volume-licensed version to a current retail version

At any time after installing Windows Server 2012, you can freely convert it between a volume-licensed version, a retail version, or an OEM version. The edition remains the same during this conversion.

To do this, from an elevated command prompt, run:

slmgr /ipk <key>

Where <key> is the appropriate volume-license, retail, or OEM product key.

Release Notes: Important Issues in Windows Server 2012 R2

These release notes address the most critical issues and information about the Windows Server 2012 R2 operating system. For information about by-design changes, new features, and fixes in this release, see documentation and announcements from the specific feature teams. For information about important steps to take before installing this release, including issues that you may need to work around, see “System Requirements and Installation Options for Windows Server 2012 R2.” Unless otherwise specified, these notes apply to all editions and installation options of Windows Server 2012 R2.

This document is continuously updated; as critical issues requiring a workaround are discovered, they are added.

Setup on virtual machines

If you create a virtual machine with the minimum supported hardware parameters (1 processor core and 512 MB RAM) and then attempt to install this release on the virtual machine, Setup will fail.

To avoid this, do one of the following:

- Allocate more than 800 MB RAM to the virtual machine you intend to install this release on. Once Setup has completed, you can change the allocation to as little as 512 MB RAM, depending on the actual server configuration.
- Interrupt the boot process of this release on the virtual machine with SHIFT+F10. In the command prompt that opens, use Diskpart.exe to create and format an installation partition. Run **Wpeutil createpagefile /path=C:\pf.sys** (assuming the installation partition you created was C:). Close the command prompt and proceed with Setup.

Add/Remove Features wizard

In two screens, the wizard refers to Windows Server 2012; the text should read “Windows Server 2012 and Windows Server 2012 R2.” There is no impact to functionality.

Internet Explorer 11

- Input Method Editor (IME) input does not accept non-Latin characters with Adobe Flash in Internet Explorer. Only Latin characters can be inserted with an IME. To avoid this, use Internet Explorer for desktop.
- If you visit a website that contains Adobe Flash Player-based content, no PlayTo endpoints are listed in the Devices charm. There is no workaround at this time.
- When you pause Adobe Flash Player-based content in Internet Explorer and switch to Internet Explorer for desktop, the content might not be visible when you return. To avoid this, do not pause content when switching to the desktop. If this has already occurred, try refreshing the web page.

Storage Spaces

If you host a shared VHDX resource on Storage Spaces and then enable deduplication, virtual machines will not boot while the shared VHDX is attached. Do not enable deduplication on volumes that host shared VHDX resources.

Trusts

The Selective Authentication feature of selective trusts is not functional. Access to resources enabled by “Allowed to Authenticate” will fail. There is no workaround at this time.

Windows Server Essentials Experience

These issues affect both Windows Server 2012 R2 Essentials and other editions of Windows Server 2012 R2 when the Essentials Experience is installed with Server Manager.

- The Windows Server Essentials Experience only works in a single-domain environment that does not include a read-only domain controller. There is no workaround at this time.
- If you install Windows Server Essentials as a virtual machine, and if your server is not connected to the network (or the DHCP service is not available) while running the Configure Windows Server Essentials wizard, Anywhere Access functionalities (such as Remote Web Access, virtual private networking, and DirectAccess) are blocked.

  To avoid this, ensure that your server has a network connection when you install Windows Server Essentials as a virtual machine and run the Configure Windows Server Essentials Wizard. If this has already occurred, manually configure the DNS forwarder settings.
- If you enable NIC teaming and then run the Anywhere Access setup wizard, auto-configuration of the router is skipped and you will receive a false “No internet connection” warning on the dashboard.

  To correct this, manually configure the router to forward traffic on port 80/443 to the address of the teamed network interface adapter. If the server is a domain controller and had the DNS server role installed, you should also ensure that DNS on the teamed NiC is set to (‘127.0.0.1’,’::1’) and that DNS forwarders are properly configured.

Work Folders

The client and server must be running the same milestone release for Work Folders to function properly. For example, if the server is running this milestone release of Windows Server 2012 R2, the client must be running the same milestone release of Windows 8.1.

3.0

Features Removed or Deprecated in Windows Server 2012 R2

The following is a list of features and functionalities in Windows Server® 2012 R2 that have either been removed from the product in the current release or are planned for potential removal in subsequent releases (“deprecated”). It is intended for IT professionals who are updating operating systems in a commercial environment. This list is subject to change in subsequent releases and may not include every deprecated feature or functionality. For more details about a particular feature or functionality and its replacement, see the documentation for that feature.

For your quick reference, following table briefly summarizes the status of features that have been removed or deprecated in either Windows Server® 2012 or Windows Server 2012 R2.

Note
This table is necessarily abbreviated; if you see a feature marked for deprecation or removal, please consult the detailed information in this topic or in Features Removed or Deprecated in Windows Server 2012.

Quick reference table

	Windows Server 2012		**Windows Server 2012 R2**	
Feature	Removed	Deprecated	Removed	Deprecated
AD FS v1 Web Agent			x	
AD FS in-place upgrade from AD FS 1.0 or “out of box” AD FS 2.0	x			
AD FS support for “Resource Group”	x			
AD FS support for NT Token mode	x			
AD FS support for using AD LDS as an authentication store	x			
AD RMS license revocation				x
AD RMS SDK				x
Application Server role				x
Built-in drivers for tape drives				x

	Windows Server 2012		Windows Server 2012 R2	
Cluster Automation Server COM API	x (made optional)		x (optional)	
Cluster.exe command-line interface	x (made optional)		x (optional)	
CertObj COM and InetInfo interfaces of the Web Server role				x
Dcpromo.exe		x		
Dfscmd.exe				x
Drivers for Jet Red RDBMS and ODBC		x		x
File Replication Service				x
GAA_FLAG_INCLUDE_TUNNEL_BINDINGORDER flat in GetAdaptersAddresses				x
Internet Information Service (IIS) 6.0 Manager				x
Layered Service Providers		x		x
IscsiVirtualDiskSnapshot and associated WMI methods				x
LPR/LPD protocol		x		x
Namespace for version 1.0 of WMI; WMIC (in WMI)		x	x	
NDIS version 5.0, 5.1, and 5.2 APIs		x	x	
Net DMA	x			
Network Access Protection (NAP)				x
Network Information Service (NIS) and Tools (in RSAT)				x
Nfsshare.exe				x
NFSv2 support				x
Oclist.exe	x			

	Windows Server 2012		Windows Server 2012 R2	
ODBC support for 16- and 32-bit applications and drivers		x		x
ODBC/OLEDB support for Microsoft Oracle		x		
ODBC/OLEDB support for SQL beyond SQL Server 7 and SQL 2000		x		x
Providers for SNMP, Win32_ServerFeature API, Active Directory, MSClus WMI1.0 (in WMI)		x		x
Recovery disk creation			x	
Remote Data Service		x		
Role Collector (Ceiprole.exe) and associated API	x			
SCSIport host-bus adapter	x			
Servermanagercmd.exe		x	x	
SIS Limited API				x
Slmgr.vbs options			x	
SMB 1.0				x
SMB.sys	x			
SMTP and associated management tools		x		x
SQLXMLX		x		x
Storage Explorer snap-in for MMC	x			
Storage Manager for SANs snap-in for MMC	x			
Subsystem for UNIX-based Applications		x	x	
Support for 32-bit cluster resource DLLs	x			
Support for hardware drivers for XDDM	x			
Support for Microsoft SQL Server prior to 7.0	x			
Support for native VGA via the PC/AT BIOS or UEFI CSM	x			
Support for Static VMQ	x			
Support for Token Rings	x			

	Windows Server 2012		Windows Server 2012 R2	
Support for Visual Studio Analyzer 2003 over ODBC, OLEDB, and ADO	x			
System Image Backup (“Windows 7 File Recovery”)			x	
Telnet server				x
VM Chimney (also called TCP Offload) (in Hyper-V)	x			
Windows Server 2003 domain and functional levels of Active Directory				x
Windows Authorization Manager (AzMan)		x	x	
Windows Help executable (WinHlp32.exe)	x			
Windows Identity Foundation 3.5				x
Windows Server Resource Manager		x	x	
Winsock Direct		x	x	
WMI root\virtualization namespace v1 (in Hyper-V)		x	x	
XDR schema elements, XSl pattern feature of MSXML3 (in XML)		x		x

Features removed from Windows Server 2012 R2

The following features and functionalities have been removed from this release of Windows Server 2012 R2. Applications, code, or usage that depend on these features will not function in this release unless you employ an alternate method.

Note
If you are moving to Windows Server 2012 R2 from a server release prior to Windows Server 2012, you should also review Features Removed or Deprecated in Windows Server 2012.

Backup and file recovery

- The File Backup and Restore feature has been removed. Use the File History feature instead.

- System Image Backup (the “Windows 7 File Recovery” feature) has been removed. Instead, use “Reset your PC.”

Drivers

Drivers for tape drives have been removed from the operating system. Instead, use the drivers provided by the manufacturer of your tape drive.

Recovery disk creation

The ability to create a recovery disk on CD or DVD has been removed. Use the Recovery Disk to USB feature.

Slmgr.vbs options

The **/stao** (sets token activation only) and **/ctao** (clears activation tokens only) options of Slmgr.vbs have been removed. These options have been replaced by more flexible activation command options.

Subsystem for UNIX-based Applications

The Subsystem for UNIX-based Applications (SUA) has been removed. If you use the SUA POSIX subsystem with this release, use Hyper-V to virtualize the server. If you use the tools provided by SUA, switch to Cygwin's POSIX emulation, or use either mingw-w64 (available from Sourceforge.net) or MinGW (available from MinGW.org) for doing a native port.

Windows Authorization Manager (AzMan)

Windows Authorization Manager (AzMan) has been removed. You might need to use new management tools for virtual machines or redesign the authorization model.

WMI root\virtualization namespace v1 (used in Hyper-V)

The WMI root\virtualization\v1 namespace has been removed. Instead use the root\virtualization\v2 namespace.

Features deprecated starting with Windows Server 2012 R2

The following features and functionalities are deprecated starting with this release. Eventually, they will be completely removed from the product, but they are still available in this release, sometimes with certain functionality removed. You should begin planning now to employ alternate methods for any applications, code, or usage that depend on these features.

Active Directory

- The Active Directory Rights Management Services (AD RMS) SDK has been deprecated. To build applications for AD RMS, migrate to AD RMS SDK 2.0, which leverages functionality exposed by the client in Msipc.dll.
- The license revocation functionality in AD RMS is deprecated. Use the protection policy to control the document lifecycle. To remove access to a particular document, set the validity time to “0” in the template, or select **Require a connection to verify a user’s permission** in Microsoft Office. Be aware that both of these options require a connection to a Rights Management Server in order to open the files.
- The File Replication Service (FRS; part of the Active Directory Domain Services role) is deprecated. You should migrate any FRS-based SYSVOLs to use Distributed File System Replication.
- The Windows Server 2003 domain and forest functional levels are deprecated. When you create a new domain or forest, you should consider using a functional level from Windows Server 2008 or newer. When you deploy Windows Server 2012 R2 into an existing Windows Server 2003 environment, you will be notified to move to a newer functional level.

Application Server

The Application Server role is deprecated and will eventually no longer be available as an installable server role. Instead, install individual features and roles separately.

COM and Inetinfo interfaces of the Web Server role

- The IIS CertObj COM interface is deprecated. Use alternate methods for managing certificates.
- The Inetinfo interface is deprecated.

DNS

The GAA_FLAG_INCLUDE_TUNNEL_BINDINGORDER flag in GetAdaptersAddresses is deprecated. There is no specific replacement.

File and storage services

- The SIS Limited API set is deprecated. Once it is removed, backups of SIS-enabled volumes on servers running Windows Server 2008 R2 or earlier operating systems will not be able to be restored to newer servers. If you use this API, you should limit the target operating system to older versions that still support the API.
- Dfscmd.exe is deprecated. Instead, use Windows PowerShell cmdlets for Distributed File System Namespaces or the Dfsutil.exe command set.
- Support for the Network File System version 2 protocol is deprecated. This means that UNMP protocol support, version 2 of the MOUNT protocol, and versions 1, 2, and 3 of the NLM protocol are also deprecated. Migrate to using NFS version 3 or 4.1.

- Nfsshare.exe is deprecated. Instead, use Windows PowerShell cmdlets in scripts for share provisioning.
- The Local Mount driver, related cmdlets (Mount-IscsiVirtualDiskSnapshot, Dismount-IscsiVirtualDiskSnapshot) and WMI methods (see “WMI” section of this document), as well as conversion of VHD files from prior to Windows Server 2012 R2 using Convert-IscsiVirtualDisk are deprecated. Change any scripts that use these cmdlets or WMI methods to use the Export-IscsiVirtualDiskSnapshot cmdlet. Then assign it to an iSCSI target and use it like any other iSCSI virtual disk. Alternately, you can access virtual disks using a local loopback iSCSI initiator.

IIS Manager 6.0

Internet Information Services (IIS) Manager 6.0 is deprecated. It has been replaced by a newer management console.

Networking

Network Access Protection (NAP) is deprecated. Other options for keeping client computers up to date and secure for remote access include DirectAccess, Windows Web Application Proxy, and various non-Microsoft solutions.

Network Information Service (NIS) and Tools (in RSAT)

The Server for Network Information Service (NIS) is deprecated. This includes the associated administration tools in Remote Server Administration Tools (RSAT). Use native LDAP, Samba Client, Kerberos, or non-Microsoft options.

RSAT: Identity management for Unix/NIS

The Server for Network Information Service (NIS) Tools option of Remote Server Administration Tools (RSAT) is deprecated. Use native LDAP, Samba Client, Kerberos, or non-Microsoft options.

SMB

SMB 1.0 is deprecated. Once this is removed, systems running Windows XP or Windows Server 2003 (or older) operating systems will not be able to access file shares. SMB 1.0 has been replaced by SMB 2.0 and newer versions.

Telnet server

Telnet server is deprecated. Instead, use Remote Desktop.

Windows Identity Foundation

Windows Identity Foundation (WIF) 3.5 is deprecated and has been replaced by WIF 4.5. You should start migrating applications that use WIF to WIF 4.5 or Windows .NET Framework 4.5.

SQL Lite

SQL Lite is deprecated. Migrate to alternatives such as SQL LocalDb.

WMI providers and methods

- The WMI version 1 provider for MSCluster is deprecated; it is being replaced by a WMI version 2 provider.
- The WMI methods related to the file server Local Mount driver and related cmdlets (WT_Snapshot.DVMount, WT_SnapShot.DVDismount, WT_Disk.GetDVMountPoints, and the WT_DVMountedPath class) are deprecated. See the “File and storage services” section of this document for more information.

4.1

Common Management Tasks and Navigation in Windows Server 2012 R2 and Windows Server 2012

Windows Server® 2012 R2, Windows® 8.1, Windows Server® 2012, and Windows® 8 feature the new Modern user interface. This topic helps you find and open common management tools, create shortcuts to frequently-used programs, run programs with elevated privileges, and perform

common tasks like signing in and out, restarting, and shutting down computers that are running Windows Server 2012 R2, Windows 8.1, Windows Server 2012, or Windows 8.

You can install Windows Server 2012 R2 or Windows Server 2012 with a minimal user interface that is well-suited to remote management. For more information, see Windows Server Installation Options.

In this topic:

Open the Start screen

Shut down or restart the computer

Lock the computer or sign out

Close a Windows app

Access Settings for the current screen

Access Control Panel

Access Administrative Tools

Create shortcuts

Open the Run dialog box

Run a program as administrator or as another user

Use common IT Pro tools:

- Open Server Manager
- Start Windows PowerShell
- Open Remote Desktop Connection
- Open Command Prompt
- Open Microsoft Management Console (MMC) and snap-ins

Keyboard shortcuts

Use keyboard shortcuts in a Remote Desktop session

Use keyboard shortcuts in Hyper-V virtual machines

Open the Start screen

The **Start** screen is the home of Windows apps. To open the **Start** screen, use one of these methods:

- Press the Windows logo key. In a virtual machine, you can press **Ctrl**+**Esc**.
- Hover the mouse cursor in the upper right corner of the screen, and then click **Start**.
- On the desktop, hover the mouse cursor in the lower left corner of the screen, and click when the thumbnail of the **Start** screen appears.

Shut down or restart the computer

To shut down the computer

1. Hover the mouse cursor in the upper right corner of the screen, and then click **Settings**.
2. Click **Power**, and then click **Shut down**.

To restart the computer

1. Hover the mouse cursor in the upper right corner of the screen, and then click **Settings**.
2. Click **Power**, and then click **Restart**.

Lock the computer or sign out

To lock the computer

- On the **Start** screen, click your user name in the upper right corner, and then click **Lock**. Alternatively, on the **Start** screen, press the Windows logo key+L.

To sign out from the computer

- On the **Start** screen, click your user name in the upper right corner, and then click **Sign out**.

Close a Windows app

When Windows apps like Internet Explorer are open but not in use, they are automatically minimized and become inactive, freeing resources for other apps. This functionality is similar to a cell phone, tablet PC, or other mobile computer. It is not necessary to close an app, but you can follow steps in this section if you want to do so.

To close a Windows app

- With the app active, hover at the top edge of the screen until the mouse cursor becomes a hand. Click and drag the app to the bottom of the screen, and then release.

Access Settings for the current screen

To open the Settings bar

- Press the Windows logo key+i to open the **Settings** bar for the current screen (for example, **Start**, the desktop, or a Windows app).
- Alternatively, hover the mouse cursor in the upper right corner of the screen, and then click **Settings**.

Access Control Panel

You can access Control Panel from the **Start** screen and from the desktop.

To open Control Panel from the Start screen

- On the **Start** screen, click **Control Panel**.

To open Control Panel from the desktop

1. On the desktop, hover the mouse cursor in the upper right corner of the screen, and then click **Settings**.
2. Click **Control Panel**.

To open common Control Panel tools by using typed commands

1. On the **Start** screen, type one of the following, and then press **Enter** to open common Control Panel management tools.
   - **ncpa.cpl** to open **Control Panel\Network and Internet\Network Connections**.
   - **sysdm.cpl** to open the **System Properties** dialog box that is available at **Control Panel\System and Security\System\Advanced System Settings**.
   - **appwiz.cpl** to open **Control Panel\Programs\Programs and Features\Uninstall or change a program**.
   - **inetcpl.cpl** to open the **Internet Properties** dialog box that is available at **Control Panel\Network and Internet\Internet Options**.

   Tip
   For more Control Panel tool commands that you can type directly on the **Start** screen, see How to run Control Panel tools by typing a command.

To add Control Panel to the desktop

1. Open Control Panel.
2. In the Control Panel **Search** box, type **desktop**.
3. In the Control Panel **Search** results, in **Display**, click **Show or hide common icons on the desktop**.
4. In **Desktop Icon Settings**, select **Control Panel**, and then click **OK**.

Access Administrative Tools

The **Administrative Tools** folder contains links to many common Microsoft Management Console (MMC) snap-ins, including **Computer Management**, **Event Viewer**, and the management tools for installed roles or features.

Tip
The **Start** screen settings (accessed by pressing the Windows logo key+i on the **Start** screen) include an option to allow or prevent tools in the **Administrative Tools** folder

from being displayed in search results and on the **Start** screen. This setting is enabled by default.

To access Administrative Tools in Server Manager

- In the Server Manager menu bar, click **Tools** to access the contents of the **Administrative Tools** folder.

To open the Administrative Tools folder from the Start screen

1. On the **Start** screen, click **Administrative Tools**. You can also type **Administrative Tools** on the **Start** screen, and then click **Administrative Tools** in the list of results.

Tip

If the **Show Administrative tools** setting is turned off, the Administrative Tools folder and its contents will not appear in the **Settings** results. The **Show Administrative tools** setting is available when you hover the mouse cursor over the upper or lower right edge of the **Start** screen, click **Settings**, and then click **Tiles**.

To open the Administrative Tools folder from the Control Panel

- Open **Control Panel**, click **System and Security**, and then click **Administrative Tools**.

Create shortcuts

To create a shortcut on the desktop

1. In File Explorer, navigate to the location of the program for which you want to create a shortcut.
2. Right-click the executable file in the program folder, and then click **Create shortcut**. Because of restricted user access rights, Windows does not allow shortcuts to be created in some folders, including the **Program Files** folder.
3. Drag the shortcut to a folder of your choice, to the desktop, or to the desktop taskbar. If the shortcut cannot be created in the location of the executable file (typically because the access rights for the **Program Files** folder are restricted), and you are prompted to select a location for the shortcut, browse to the **Desktop** folder.

To pin a program to the desktop taskbar from the Start screen

1. On the **Start** screen, search for or navigate to the app that you want to pin to the desktop taskbar.
2. Right-click the app tile, and in the app bar, click **Pin to taskbar**.

To pin a program to the desktop taskbar from File Explorer

1. Open File Explorer.

2. Navigate to the folder where the program that you want to pin to the desktop taskbar is located.
3. Right-click the executable file in the program folder, and then click **Pin to Taskbar**.

To pin a program or folder to the Start screen

1. Open File Explorer.
2. Navigate to the program or folder that you want to pin to the **Start** screen.
3. Right-click the executable file or folder, and then click **Pin to Start**.

Open the Run dialog box

To open the Run dialog box

- On the desktop, press the **Windows logo key+R** to open the **Run** dialog box.

  Alternatively, on the **Start** screen, type **Run**, and then press **Enter**.

Run a program as administrator or as another user

To run a program as administrator from the Start screen

1. On the **Start** screen, navigate to the app that you want to run as Administrator.
2. Right-click the app tile, and in the app bar, click **Run as administrator**.

To run a program as administrator from the desktop

1. Right-click the executable file in File Explorer, or right-click the program shortcut on the desktop.
2. Click **Run as administrator**.

To run a program as another user

- Do one of the following.
  - Add the **Run as a different user** command to the app bar by enabling the following Group Policy setting: `User Configuration/Administrative Templates/Start Menu and Taskbar/Show "Run as different user" command on Start`. To start Local Group Policy Editor, on the **Start** screen, type **gpedit.msc**, and then press **Enter**.
  - Use the **runas** command from a command prompt. For more information about how to use the **runas** command, at a command prompt, type **runas /?**, and then press **Enter**.

Open Server Manager

By default, Server Manager starts when a member of the **Administrators** group signs in to a computer that is running Windows Server 2012 R2 or Windows Server 2012. If Server Manager is not already open, if you are a standard (non-Administrator) user on the server, or if administrators have changed Server Manager default settings so that it does not open automatically at sign-in, open Server Manager by using procedures in this section.

To open Server Manager from the Start screen

- On the **Start** screen, click **Server Manager**.

Note

If the **Show Administrative tools** setting is disabled, the Server Manager tile does not appear on the **Start** screen.

To open Server Manager from the desktop

- On the taskbar, click **Server Manager**.

Start Windows PowerShell

To start Windows PowerShell™ from the Start screen

- On the **Start** screen, click **Windows PowerShell**.

To start Windows PowerShell from the desktop

- On the taskbar, click **Windows PowerShell**.

To start Windows PowerShell with elevated user rights (Run as administrator)

- To run Windows PowerShell as an administrator from the **Start** screen, right-click the **Windows PowerShell** tile, and in the app bar, click **Run as administrator**.
- To run Windows PowerShell as an administrator from the desktop, right-click the **Windows PowerShell** shortcut in the taskbar, and then click **Run as Administrator**.

Open Remote Desktop Connection

To open Remote Desktop Connection from the Start screen

1. On the **Start** screen, type **mstsc**.
2. In the **Search Apps** results, click **mstsc**.

To open Remote Desktop Connection from the desktop

1. On the desktop, press the **Windows logo key+R** to open the **Run** dialog box.
2. In the **Run** dialog box, type **mstsc**, and then press **Enter**.

Open Command Prompt

To open Command Prompt from the Start screen

1. On the **Start** screen, type **cmd**.
2. In the **Apps** results, click **cmd**.

To open Command Prompt from the desktop

1. On the desktop, press the **Windows logo key+R** to open the **Run** dialog box.
2. In the **Run** dialog box, type **cmd**, and then press **Enter**.

To open Command Prompt with elevated user rights (Run as administrator)

- Do one of the following.
  - To run Command Prompt as an administrator from the **Start** screen on Windows Server 2012 R2, type **cmd**, right-click **Command Prompt** in the **Search** results, and on the shortcut menu, click **Run as administrator**.
  - To run Command Prompt as an administrator from the **Start** screen on Windows Server 2012, type **cmd**, right-click **Command Prompt** in the **Apps** results, and then in the taskbar, click **Run as Administrator**.

Open Microsoft Management Console (MMC) and snap-ins

To open MMC from the Start screen

1. On the **Start** screen, type **mmc**.
2. In the **Apps** or **Search** results, click **mmc**.

To open MMC from the desktop

1. On the desktop, press the **Windows logo key+R** to open the **Run** dialog box.
2. In the **Run** dialog box, type **mmc**, and then press **Enter**.

To open an MMC snap-in from the Start screen

1. On the **Start** screen, type the executable file name of a snap-in.

   Example: Type **gpedit.msc**.
2. When the snap-in is displayed in the **Apps** or **Search** results, click the tile.

To open an MMC snap-in from the desktop

1. On the desktop, press the **Windows logo key+R** to open the **Run** dialog box.
2. Type the executable file name of a snap-in, and then press **Enter**.

   Example: Type **gpedit.msc**.

To open Event Viewer

- Do one of the following.
  a. To open Event Viewer from the **Start** screen, type **eventvwr.msc**, and then press **Enter**.
  b. To open Event Viewer from the desktop, press the **Windows logo key+R** to open the **Run** dialog box, type **eventvwr.msc**, and then press **Enter**.

Tip

Alternatively, you can open a technology-specific snap-in from the **Administrative Tools** folder. For information about how to access the **Administrative Tools** folder, see Access Administrative Tools in this topic.

Keyboard shortcuts

This section provides keyboard shortcuts that are unchanged from Windows 7 and Windows Server 2008 R2, and a table of shortcuts that are new for the Modern user interface in Windows 8 and Windows Server 2012.

Note

Keyboard shortcuts require certain settings and environments to work in a Remote Desktop or virtual machine session. For more information, see Use keyboard shortcuts in a Remote Desktop session and Use keyboard shortcuts in Hyper-V virtual machines in this topic.

Keyboard shortcuts that are unchanged from Windows 7 or Windows Server 2008 R2

Key	Windows 7 or Windows Server 2008 R2 Functionality
Windows logo key	Display or hide the **Start** screen
Windows logo key+left arrow	Dock active window of a desktop app to left half of screen (no effect on Windows Store apps)
Windows logo key+right arrow	Dock active window of a desktop app to right half of screen (no effect on Windows Store apps)
Windows logo key+up arrow	Maximize active desktop app window (no effect

Key	Windows 7 or Windows Server 2008 R2 Functionality
	on Windows Store apps)
Windows logo key+down arrow	Restore or minimize active desktop app window (no effect on Windows Store apps)
Windows logo key+**Shift**+up arrow	Maximize active desktop app window vertically, maintaining width (no effect on Windows Store apps)
Windows logo key+**Shift**+down arrow	Restore or minimize active desktop app window vertically (no effect on Windows Store apps)
Windows logo key+**Shift**+left arrow	Move active desktop app window to monitor on the left (no effect on Windows Store apps)
Windows logo key+**Shift**+right arrow	Move active desktop app window to monitor on the right (no effect on Windows Store apps)
Windows logo key+**P**	Display projection options
Windows logo key+**Home**	Minimize all non-active windows, restore on second keystroke (no effect on Windows apps)
Windows logo key+<number>	Open or switch to the program located at the specified position on the taskbar (Example: Windows logo key+1 to open first program.)
Windows logo key+**Shift**+<number>	Open a new or additional session in the program located at the specified position on the taskbar
Windows logo key+**Ctrl**+**Shift**+<number>	Open a new or additional session of the program located at the specified position on the taskbar, running as Administrator
Windows logo key+**B**	Set focus in the notification area.
Windows logo key+**Break**	Display the System Properties dialog box.
Windows logo key+**D**	Show the desktop, restore on second keystroke (no effect on Windows apps)
Windows logo key+**E**	Open File Explorer to display the **Computer** page
Windows logo key+**Ctrl**+**F**	Search for computers (if you are on a network)
Windows logo key+**G**	Cycle through installed Windows Desktop Gadgets

Key	Windows 7 or Windows Server 2008 R2 Functionality
Windows logo key+**L**	Lock your computer (if you are connected to a network domain), or switch users (if you are not connected to a network domain)
Windows logo key+**M**	Minimize all windows
Windows logo key+**Shift**+**M**	Restore minimized windows to the desktop (no effect on Windows apps)
Windows logo key+**R**	Open the **Run** dialog box.
Windows logo key+**T**	Set focus on the taskbar and cycle through programs
Windows logo key+**Alt**+**Enter**	Open Windows Media Center
Windows logo key+**U**	Open Ease of Access Center
Windows logo key+**X**	Open Windows Mobility Center
Windows logo key+**F1**	Open Windows Help and Support
Windows logo key+**N**	Creates a new note (OneNote)
Windows logo key+**S**	Opens screen clipper (OneNote)
Windows logo key+**Q**	Opens Lync (Lync)
Windows logo key+**A**	Accepts incoming call (Lync)
Windows logo key+**X**	Rejects incoming call (Lync)
Windows logo key+Minus (**-**)	Zoom out (Magnifier)
Windows logo key+Plus (**+**)	Zoom in (Magnifer)
Windows logo key+**Esc**	Close Magnifier

Keyboard shortcuts that are new for Windows Server 2012 R2, Windows 8.1, Windows Server 2012, and Windows 8

Key	Windows Server 2012 R2, Windows 8.1, Windows 8, or Windows Server 2012 Functionality
Windows logo key+**spacebar**	Switch input language and keyboard layout
Windows logo key+**O**	Locks device orientation
Windows logo key+**Y**	Temporarily displays the desktop
Windows logo key+**V**	Cycles through notifications

Key	Windows Server 2012 R2, Windows 8.1, Windows 8, or Windows Server 2012 Functionality
Windows logo key+**Shift**+**V**	Cycles through notifications in reverse order
Windows logo key+**Enter**	Opens Narrator
Windows logo key+**PgUp**	Moves Windows apps to the monitor on the left
Windows logo key+**PgDown**	Moves Windows apps to the monitor on the right
Windows logo key+**Shift**+period (**.**)	Moves the gutter to the left (snaps an application)
Windows logo key+period (**.**)	Moves the gutter to the right (snaps an application)
Windows logo key+**C**	Opens charms bar
Windows logo key+**I**	Opens Settings pane
Windows logo key+**K**	Opens Devices pane
Windows logo key+**H**	Opens Share pane
Windows logo key+**Q**	Opens Search pane
Windows logo key+**W**	Opens Settings Search app
Windows logo key+**F**	Opens File Search app
Windows logo key+**Tab**	Cycles through Windows apps
Windows logo key+**Shift**+**Tab**	Cycles through Windows apps in reverse order
Windows logo key+**Ctrl**+**Tab**	Cycles through Windows apps and snaps them as they are cycled
Windows logo key+**Z**	Opens app bar

Use keyboard shortcuts in a Remote Desktop session

Before you connect to a Remote Desktop (also known as RDP) session, you can configure the session to accept Windows key combinations, whether the session is contained within a window, or occupies the full screen.

To apply keyboard shortcuts to a Remote Desktop session

1. If the Remote Desktop Connection dialog box is not already open, open it by typing **mstsc** on the **Start** screen, and then pressing **Enter**.
2. On the Remote Desktop Connection dialog box, click **Show Options** to display

connection setting tabs.

3. In the **Keyboard** area of the **Local Resources** tab, select one of the following from the **Apply Windows key combinations** drop-down list.
   - To apply keyboard shortcuts to a full-screen Remote Desktop session, select **Only when using the full screen**.
   - To apply keyboard shortcuts to a Remote Desktop session that is contained within a window, select **On the remote computer**.
4. When you are finished configuring other settings for your Remote Desktop session, click **Connect** to connect to the session and start working, or click **Save** on the **General** tab to save your connection settings as an RDP file that you can use for future connections.

Use keyboard shortcuts in Hyper-V virtual machines

Before you start a virtual machine connection, you can apply Windows key combinations to virtual machine connections on a physical host computer by editing the Hyper-V settings for the physical computer in the Hyper-V Manager console.

Note
The setting in this procedure is selected by default if the Hyper-V host computer is running Windows Server 2012 R2 or Windows Server 2012. If the host computer is running Windows 8.1, Windows 8, Windows Server 2008 R2, or Windows Server 2008, you must change the setting to apply Windows key combinations to virtual machine connections.

To apply keyboard shortcuts to new virtual machine connections

1. Open the Hyper-V Manager snap-in if it is not already open.
   - If you are running Remote Server Administration Tools for Windows 8.1 or Windows 8, or you are running Windows Server 2012 R2 or Windows Server 2012, open Server Manager, and then open **Hyper-V Manager** from the **Tools** menu in Server Manager.
   - On the **Start** screen, click **Hyper-V Manager**.
   - If the Hyper-V Manager tile is not on the **Start** screen, type all or part of the name, **Hyper-V Manager** until the Hyper-V Manager tile appears on the **Start** screen.
2. In the tree pane, right-click the physical host computer, and then click **Hyper-V Settings**.
3. In the **User** area of the navigation pane, click **Keyboard** to display keyboard shortcut settings.
4. Select **Use on the virtual machine** to allow new virtual machine connections to accept Windows key combinations from the physical computer. Click **OK** to save your changes and close the Hyper-V Settings dialog box.

   Note
   This setting does not apply to virtual machine connections that are already open.

Installing Windows Server 2012

This document provides information about installing the Windows Server 2012 operating system, including any known issues that you may need to work around before starting an installation. It also provides information that you can use to troubleshoot problems that may occur during the installation. For information about serious known issues that you may need to work around after installation is complete, see the release notes, available at the same location as this document.

Setup works in several stages. You will be prompted for some basic information, and then Setup will copy files and restart the computer. Setup concludes by presenting a menu for Initial Configuration Tasks, which you can use to configure your server for your specific needs.

Preinstallation information

System requirements

The following are estimated system requirements for the Windows Server 2012. If your computer has less than the "minimum" requirements, you will not be able to install this product correctly. Actual requirements will vary based on your system configuration and the applications and features you install.

Processor

Processor performance depends not only on the clock frequency of the processor, but also on the number of processor cores and the size of the processor cache. The following are the processor requirements for this product:

- **Minimum**: 1.4 GHz 64-bit processor

RAM

The following are the estimated RAM requirements for this product:

- **Minimum**: 512 MB

Disk space requirements

The following are the estimated **minimum** disk space requirements for the system partition.

- **Minimum**: 32 GB

  Notes
  Be aware that 32 GB should be considered an absolute minimum value for successful installation. The system partition will need extra space for any of the following circumstances:

  - If you install the system over a network.

- Computers with more than 16 GB of RAM will require more disk space for paging, hibernation, and dump files.

Other requirements

You also need to have the following:

- DVD drive
- Super VGA (800 x 600) or higher-resolution monitor
- Keyboard and Microsoft® mouse (or other compatible pointing device)
- Internet access (fees may apply)

Important information for x64-based operating systems

Ensure that you have updated and digitally signed kernel-mode drivers for Windows Server 2012

If you install a Plug and Play device, you may receive a warning if the driver is not digitally signed. If you install an application that contains a driver that is not digitally signed, you will not receive an error during Setup. In both cases, Windows Server 2012 will not load the unsigned driver.

If you are not sure whether the driver is digitally signed, or if you are unable to boot into your computer after the installation, use the following procedure to disable the driver signature requirement. This procedure enables your computer to start correctly, and the unsigned driver will load successfully.

To disable the signature requirement for the current boot process:

1. Restart the computer and during startup, press F8.
2. Select **Advanced Boot Options**.
3. Select **Disable Driver Signature Enforcement**.
4. Boot into Windows® and uninstall the unsigned driver.

For more information, see http://go.microsoft.com/fwlink/?LinkId=66577.

Before you start Setup

Before you install Windows Server 2012, follow the steps in this section to prepare for the installation.

- **Disconnect UPS devices.** If you have an uninterruptible power supply (UPS) connected to your destination computer, disconnect the serial cable before running Setup. Setup automatically attempts to detect devices that are connected to serial ports, and UPS equipment can cause issues with the detection process.
- **Back up your servers.** Your backup should include all data and configuration information that is necessary for the computer to function. It is important to perform a backup of configuration information for servers, especially those that provide network infrastructure, such as Dynamic Host Configuration Protocol (DHCP) servers. When you perform the backup, be sure to include the boot and system partitions and the system state data. Another

way to back up configuration information is to create a backup set for Automated System Recovery.

- **Disable your virus protection software.** Virus protection software can interfere with installation. For example, it can make installation much slower by scanning every file that is copied locally to your computer.
- **Provide mass storage drivers.** If your manufacturer has supplied a separate driver file, save the file to a floppy disk, CD, DVD, or Universal Serial Bus (USB) flash drive in either the root directory of the media or the **amd64** folder. To provide the driver during Setup, on the disk selection page, click **Load Driver** (or press F6). You can browse to locate the driver or have Setup search the media.
- **Be aware that Windows Firewall is on by default.** Server applications that must receive unsolicited inbound connections will fail until you create inbound firewall rules to allow them. Check with your application vendor to determine which ports and protocols are necessary for the application to run correctly.

  For more information about Windows Firewall, see http://go.microsoft.com/fwlink/?LinkID=84639.

Supported upgrade paths

The table below briefly summarizes supported upgrade paths to Windows Server 2012. For more details on upgrade paths, important caveats to upgrade, and additional information about evaluation versions, see http://go.microsoft.com/fwlink/?LinkId=260917.

If you do not see your current version in the left column, upgrading to this release of Windows Server 2012 is not supported.

If you see more than one edition in the right column, upgrade to either edition from the same starting version is supported.

If you are running:	You can upgrade to these editions:
Windows Server 2008 Standard with SP2 or Windows Server 2008 Enterprise with SP2	Windows Server 2012 Standard, Windows Server 2012 Datacenter
Windows Server 2008 Datacenter with SP2	Windows Server 2012 Datacenter
Windows Web Server 2008	Windows Server 2012 Standard
Windows Server 2008 R2 Standard with SP1 or Windows Server 2008 R2 Enterprise with SP1	Windows Server 2012 Standard, Windows Server 2012 Datacenter
Windows Server 2008 R2 Datacenter with SP1	Windows Server 2012 Datacenter
Windows Web Server 2008 R2	Windows Server 2012 Standard

Release Notes: Important Issues in Windows Server 2012

These release notes address the most critical issues and information about the Windows Server® 2012 operating system. For information about by-design changes, new features, and fixes in this release, see documentation and announcements from the specific feature teams. For information about important steps to take before installing this release, including issues that you may need to work around, see Installing Windows Server 2012, a document available at the same location as this document. Unless otherwise specified, these notes apply to all editions and installation options of the Windows Server 2012.

This document is continuously updated; as critical issues requiring a workaround are discovered, they are added.

Upgrade

If you upgrade from a Full installation of Windows Server® 2008 or Windows Server® 2008 R2 to Windows Server 2012 in Server with a GUI mode, and then switch Windows Server 2012 to Server Core mode, conversion back to Server with a GUI mode will fail.

To avoid this, delete these registry keys with the following commands:

reg delete HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\WINEVT\Publishers\{bc2eeeec-b77a-4a52-b6a4-dffb1b1370cb}

reg delete HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\WINEVT\Publishers\{57e0b31d-de8c-4181-bcd1-f70e880b49fc}

reg delete HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\WINEVT\Publishers\{8c9dd1ad-e6e5-4b07-b455-684a9d879900}

After running these commands, restart the upgrade.

Evaluation Versions and Upgrade Options for Windows Server 2012

This document summarizes key information about evaluation versions of Windows Server® 2012, including where to obtain them, the limits on their use, and how to convert them to full retail versions. It also summarizes the supported upgrade paths from previously licensed retail versions of Windows Server to Windows Server 2012.

Evaluation versions of Windows Server 2012

Fully functional time-limited evaluation versions of Windows Server 2012 are available for the following editions:

- Windows Server 2012 Standard
- Windows Server 2012 Datacenter
- Windows Server® 2012 Essentials

These evaluation versions are 64-bit only and can be installed with the Server Core option or the Server with a GUI option. For more information about these installation options, how to convert between them, and how to use the new Minimal Server Interface and Features on Demand, see http://technet.microsoft.com//library/hh831786.

For all editions, you have 10 days to complete online activation, at which point the evaluation period begins and runs for 180 days. During the evaluation period, a notification on the Desktop displays the days remaining the evaluation period (except in Windows Server 2012 Essentials). You can also run **slmgr.vbs /dlv** from an elevated command prompt to see the time remaining.

Where to find evaluation versions

You can get evaluation versions by the following methods:

- Windows Server 2012 Standard; Windows Server 2012 Datacenter: from the TechNet Evaluation Center (http://technet.microsoft.com/en-US/evalcenter/hh670538.aspx). These editions are also available as pre-created VHDs for use in virtualized environments.
- Windows Server 2012 Essentials: from http://go.microsoft.com/fwlink/p/?LinkId=266340

Limits of evaluation versions

All evaluation versions are fully functional during the evaluation period, although booting to Safe mode is not available. The Windows Server 2012 Standard and Windows Server 2012 Datacenter editions come with the activation key pre-installed. After the 180-day evaluation period elapses, the server warns you in various ways depending on the edition:

Windows Server 2012 Standard; Windows Server 2012 Datacenter:

- The following warning appears on the Desktop: **Windows License is expired**
- When you log on to Windows, you are prompted with the following options:
  - Activate now
  - Ask me later
- The system shuts down every hour.
- The only updates that can be installed are security updates.
- Event ID 100 from source WLMS “The license period for this installation of Windows has expired. The operating system will shut down every hour.” appears in the Application log.

Windows Server 2012 Essentials: you receive warnings on the Desktop and on the dashboard, but the server does not shut down.

Converting evaluation versions of Windows Server 2012 to full retail versions

Most evaluation versions can be converted to full retail versions, but the method varies slightly depending on the edition. Before you attempt to convert the version, verify that your server is actually running an evaluation version. To do this, do either of the following:

1. From an elevated command prompt, run **slmgr.vbs /dlv**; evaluation versions will include “EVAL” in the output.
2. From the **Start** screen, open **Control Panel**. Open **System and Security**, and then **System**. View Windows activation status in the Windows activation area of the System page. Click **View details in Windows activation** for more information about your Windows activation status.

If you have already activated Windows, the Desktop shows the time remaining in the evaluation period.

If the server is running a retail version instead of an evaluation version, see the “Upgrading previous licensed versions” section of this document for instructions to upgrade to Windows Server 2012.

For Windows Server 2012 Essentials: You can convert to the full retail version by entering a retail, volume license, or OEM key in the command slmgr.vbs.

If the server is running an evaluation version of Windows Server 2012 Standard or Windows Server 2012 Datacenter, you can convert it to a retail version as follows:

1. If the server is a domain controller, you cannot convert it to a retail version. In this case, install an additional domain controller on a server that runs a retail version and remove AD DS from the domain controller that runs on the evaluation version. For more information, see http://technet.microsoft.com/en-us/library/hh994618.aspx.
2. Read the license terms.
3. From an elevated command prompt, determine the current edition name with the command **DISM /online /Get-CurrentEdition**. Make note of the edition ID, an abbreviated form of the edition name. Then run **DISM /online /Set-Edition:<edition ID> /ProductKey:XXXXX-XXXXX-XXXXX-XXXXX-XXXXX /AcceptEula**, providing the edition ID and a retail product key. The server will restart twice.

For the evaluation version of Windows Server 2012 Standard, you can also convert to the retail version of Windows Server 2012 Datacenter in one step using this same command and the appropriate product key.

Tip

For more information about Dism.exe, see http://go.microsoft.com/fwlink/?LinkId=192466.

Upgrading previous retail versions of Windows Server to Windows Server 2012

The table below briefly summarizes which already licensed (that is, not evaluation) Windows operating systems can be upgraded to which editions of Windows Server 2012.

Note the following general guidelines for supported paths:

- In-place upgrades from 32-bit to 64-bit architectures are not supported. All editions of Windows Server 2012 are 64-bit only.
- In-place upgrades from one language to another are not supported.
- In-place upgrades from one build type (fre to chk, for example) are not supported.
- If the server is a domain controller, see http://technet.microsoft.com/library/hh994618.aspx for important information.
- Upgrades from pre-release versions of Windows Server 2012 (such as the Release Candidate) are not supported. Perform a clean installation to Windows Server 2012.

- Upgrades that switch from a Server Core installation to the Server with a GUI mode of Windows Server 2012 in one step (and vice versa) are not supported. However, after upgrade is complete, Windows Server 2012 allows you to switch freely between Server Core and Server with a GUI modes. For more information about these installation options, how to convert between them, and how to use the new Minimal Server Interface and Features on Demand, see http://technet.microsoft.com/en-us/library/hh831786.
- If you do not see your current version in the left column, upgrading to this release of Windows Server 2012 is not supported.

  If you see more than one edition in the right column, upgrade to either edition from the same starting version is supported.

If you are running:	You can upgrade to these editions:
Windows Server 2008 Standard with SP2 or Windows Server 2008 Enterprise with SP2	Windows Server 2012 Standard, Windows Server 2012 Datacenter
Windows Server 2008 Datacenter with SP2	Windows Server 2012 Datacenter
Windows Web Server 2008	Windows Server 2012 Standard
Windows Server 2008 R2 Standard with SP1 or Windows Server 2008 R2 Enterprise with SP1	Windows Server 2012 Standard, Windows Server 2012 Datacenter
Windows Server 2008 R2 Datacenter with SP1	Windows Server 2012 Datacenter
Windows Web Server 2008 R2	Windows Server 2012 Standard

Per-server-role considerations for upgrading

Even in supported upgrade paths from previous retail versions to Windows Server 2012, certain server roles that are already installed might require additional preparation or actions for the role to continue functioning after the upgrade. The following table summarizes these considerations.

Server role	Upgrade information
Active Directory	**Active Directory Domain Services (AD DS):** Active Directory domains can be upgraded by upgrading the operating system of existing domain controllers or by replacing existing domain controllers with domain controllers that run Windows Server 2012. For more information, see Deploy Active Directory Domain Services (AD DS) in Your Enterprise (http://go.microsoft.com/fwlink/?LinkId=262195). **Active Directory Lightweight Directory**

Server role	Upgrade information
	Services (AD LDS): For more information, see Upgrading from ADAM to AD LDS (http://go.microsoft.com/fwlink/?LinkId=186351).
Active Directory Federation Services (AD FS)	For more information about upgrading AD FS from Windows Server 2008 R2 to Windows Server 2012, see http://technet.microsoft.com/library/jj647765.aspx
Active Directory Rights Management Services (AD RMS)	You can perform an in-place upgrade from either Windows Server 2008 or Windows Server 2008 R2 to Windows Server 2012. After completing upgrade of your operating system for any servers running the AD RMS server role, you will need to run the AD RMS Upgrade wizard to upgrade your AD RMS cluster and ensure consistency. Otherwise, your AD RMS cluster might not be in a consistent state. The only other consideration when upgrading that you should be aware of when upgrading from these versions of the Windows Server operating system is that if the Windows Internal Database (WID) was previously selected for use to support your AD RMS database needs, that configuration will block your upgrade to Windows Server 2012 and require you to take additional steps. To unblock your upgrade to Windows Server 2012 you must first uninstall the AD RMS server role and migrate the existing WID instance to a SQL Server instance. For more information, see http://go.microsoft.com/fwlink/?LinkId=229299.
Fax Server	See http://technet.microsoft.com/library/jj134193.aspx.
File and Storage Services	After you upgrade a Windows Server 2008 R2-based server that has DFS Management installed, you must reinstall the DFS Management Tools on the server. To install the DFS Management Tools, run the following Windows PowerShell cmdlet as an administrator: `Install-WindowsFeature RSAT-DFS-Mgmt-Con`

Server role	Upgrade information
	You can also use the Add Roles and Features Wizard in Server Manager. On the **Features** page of the wizard, expand **Remote Server Administration Tools**, expand **Role Administration Tools**, expand **File Services Tools**, and then select the **DFS Management Tools** check box.
Hyper-V	Shut down and save all virtual machines prior to starting upgrade. For additional information, see http://technet.microsoft.com /library/hh831531
Print and Document Services	See http://technet.microsoft.com/library/jj134150.
Remote Access	Routing and Remote Access Service (RRAS) was a role service in Windows Server operating systems prior to Windows Server 2012 that enabled you to use a computer as an IPv4 or IPv6 router, as an IPv4 network address translation (NAT) router, or as a remote access server that hosted dial-up or virtual private network (VPN) connections from remote clients. Now, that feature has been combined with DirectAccess to make up the Remote Access server role in Windows Server 2012. For information about migration from Windows Server 2008 R2 and other versions prior to Windows Server 2012, see http://technet.microsoft.com/library/hh831423.aspx
Remote Desktop Services	Windows Server® 2008 R2 Remote Desktop Services role services cannot be migrated to Windows Server 2012, however an existing Windows Server 2008 R2 RD Session Host server deployment can be integrated into a Windows Server 2012 RDS deployment. The Windows Server 2012 RD Web Access can be configured to point to an existing Windows Server 2008 R2 RD Session Host server farm. Desktops and RemoteApp programs published on the Windows Server® 2008 R2 RD Session Host server farm can be accessed from a Windows Server 2012 RD Web Access server.The Following steps need to be completed in order to add an existing Windows Server® 2008 R2 RD Session Host server farm to

Server role	Upgrade information
	a Windows Server 2012 Remote Desktop Services deployment: • Populate the TS Web Access Computers Security Group. • Configure Windows Server 2008 R2 Session Host servers with the right certificate to sign RDP files. • Pointing a Windows Server 2012 RD Web Access server to a Windows Server® 2008 R2 RD Session Host server farm.
Volume Activation Services	With Active Directory-based Activation, you do not need an additional host server; your existing domain controllers can support activation clients, with the following limitations: • Active Directory-based Activation cannot be configured on read-only domain controllers. • Active Directory-based Activation cannot be used with non-Microsoft directory services. • AD DS must be at the Windows Server 2012 schema level to store activation objects. Domain controllers running earlier versions of Windows Server can activate clients after their schemas have been updated using the Windows Server 2012 version of Adprep.exe. For more information, see What's New in Active Directory Domain Services Installation and Removal.
Web Server (IIS)	No functionality has been removed or changed. Web applications that work in IIS 7.0 run normally in IIS 8.0.

Converting existing Windows Server 2012 versions

At any time after installing Windows Server 2012, you can run Setup to repair the installation (sometimes called “repair in place”) or, in certain cases, to convert to a different edition.

You can run Setup to perform a “repair in place” on any edition of Windows Server 2012; the result will be the same edition you started with.

For Windows Server 2012 Standard, you can convert the system to Windows Server 2012 Datacenter as follows: From an elevated command prompt, determine the current edition name with the command **DISM /online /Get-CurrentEdition**. Make note of the edition ID, an

abbreviated form of the edition name. Then run **DISM /online /Set-Edition:<edition ID> /ProductKey:XXXXX-XXXXX-XXXXX-XXXXX-XXXXX /AcceptEula**, providing the edition ID and a retail product key. The server will restart twice.

For Windows Server 2012 Essentials, you can run Setup and convert it to Windows Server 2012 Standard by providing the appropriate retail license key.

Windows Server Installation Options

This document summarizes the differences between the installation options available for Windows Server® 2012, including the features that are installed with each option, the management options available after installation, and how to switch between the installation options during use. It also explains the differences between the Server Graphical Shell and the Minimal Server Interface and how to switch between them. In addition, it discusses how to use Features on Demand to further reduce the disk footprint by including the binary files for only the server roles you actually use.

Installation options description

When you install Windows Server 2012, you can choose between **Server Core Installation** and **Server with a GUI**. The “Server with a GUI” option is the Windows Server 2012 equivalent of the Full installation option available in Windows Server 2008 R2. The “Server Core Installation” option reduces the space required on disk, the potential attack surface, and especially the servicing requirements, so we recommend that you choose the Server Core installation unless you have a particular need for the additional user interface elements and graphical management tools that are included in the “Server with a GUI” option. For this reason, the Server Core installation is now the default. Because you can freely switch between these options at any time later, one approach might be to initially install the Server with a GUI option, use the graphical tools to configure the server, and then later switch to the Server Core Installation option.

An intermediate state is possible where you start with a Server with a GUI installation and then remove Server Graphical Shell, resulting in a server that comprises the “Minimal Server Interface,” Microsoft Management Console (MMC), Server Manager, and a subset of Control Panel. See the “Minimal Server Interface” section of this document for more information.

In addition, after installation of either option is complete, you can completely remove the binary files for server roles and features that you do not need, thereby conserving disk space and reducing the attack surface still further. See the “Features on Demand” section of this document for more information.

A server in Minimal Server Interface mode is about 300 MB smaller than the same server in Server with a GUI mode. A server in Server Core mode is about 4 GB smaller than the same server in Server with a GUI mode. For the smallest possible installation footprint, start with a Server Core installation and then completely remove any server roles or features you do not need by using Features on Demand.

If you choose the Server Core Installation option

With this option, the standard user interface (the “Server Graphical Shell”) is not installed; you manage the server using the command line, Windows PowerShell, or by remote methods.

- **User interface:** command prompt (Server Graphical Shell is not installed)
- **Install, configure, uninstall server roles locally:** at a command prompt with Windows PowerShell.
- **Install, configure, uninstall server roles remotely:** with Server Manager, Remote Server Administration Tools (RSAT), or Windows PowerShell.

  Note
  For RSAT, you must use the Windows 8 version.
- **Microsoft Management Console:** not available locally.
- **Desktop Experience:** not available.
- **Server roles available:**
  - Active Directory Certificate Services
  - Active Directory Domain Services
  - DHCP Server
  - DNS Server
  - File Services (including File Server Resource Manager)
  - Active Directory Lightweight Directory Services (AD LDS)
  - Hyper-V
  - Print and Document Services
  - Streaming Media Services
  - Web Server (including a subset of ASP.NET)
  - Windows Server Update Server
  - Active Directory Rights Management Server
  - Routing and Remote Access Server and the following sub-roles:
    - Remote Desktop Services Connection Broker
    - Licensing
    - Virtualization
- **To convert to a Server with GUI installation with Windows PowerShell:** follow the steps in the procedure below.

  Note
  All cmdlets must be run from an elevated Windows PowerShell prompt.

To use Windows PowerShell to convert from a Server Core installation to a Server with a GUI installation

1. Determine the index number for a Server with a GUI image (for example, **SERVERDATACENTER**, not **SERVERDATACENTERCORE**) with `Get-WindowsImage -ImagePath <path to wim>\install.wim`.
2. Run `Install-WindowsFeature Server-Gui-Mgmt-Infra,Server-Gui-Shell –Restart –Source c:\mountdir\windows\winsxs`
3. Alternatively, if you want to use Windows Update as the source instead of a WIM file, use this Windows PowerShell cmdlet:

   ```
   Install-WindowsFeature Server-Gui-Mgmt-Infra,Server-Gui-Shell –Restart
   ```

If you choose the Server with a GUI option

With this option, the standard user interface and all tools are installed. Server roles and features are installed with Server Manager or by other methods.

- **User interface:** standard graphical user interface (“Server Graphical Shell”). The Server Graphical Shell includes the new Windows 8 shell, but does not include the Windows Store or support for Windows Store apps. To enable support for the Windows Store and Windows Store apps, install the Desktop Experience feature.
- **Install, configure, uninstall server roles locally:** with Server Manager or with Windows PowerShell

  Install, configure, uninstall server roles remotely: with Server Manager, Remote Server, RSAT, or Windows PowerShell
- **Microsoft Management Console:** installed
- **Desktop Experience:** installable with Server Manager or Windows PowerShell
- **To convert to a Server Core installation with Windows PowerShell:** run the following cmdlet:

  ```
  Uninstall-WindowsFeature Server-Gui-Mgmt-Infra -Restart
  ```

If you initially install with the Server with a GUI option and then use the above command to convert to a Server Core installation, you can later revert to a Server with a GUI installation without specifying a source. This is because the necessary files remain stored on the disk, even though they are no longer installed. For more information, and for instructions to completely remove the Server with a GUI files from disk, see the “Features on Demand” section of this document.

If you convert to a Server Core installation, Windows features, server roles, and GUI management tools that require a Server with a GUI installation will be uninstalled automatically. You can specify the `-WhatIf` option in Windows PowerShell to see exactly which features will be affected by the conversion.

Minimal Server Interface

In Windows Server 2012, you can remove the Server Graphical Shell, resulting in the “Minimal Server Interface.” This is similar to a Server with a GUI installation, but Internet Explorer 10,

Windows Explorer, the desktop, and the Start screen are not installed. Microsoft Management Console (MMC), Server Manager, and a subset of Control Panel are still present.

Starting with a Server with a GUI installation, you can convert to the Minimal Server Interface at any time using Server Manager.

Note

When you change any of these options, you will have to restart the server for the change to take effect.

See the table below for a summary of which selections to make in Server Manager (or cmdlets to use in Windows PowerShell) in order to get a given installation state:

To reach the installation state in each column…	Server Core installation option	Minimal Server Interface	Server with a GUI installation option	Desktop Experience feature installed
Select these features in Server Manager:	none	Graphical Management Tools and Infrastructure	Graphical Management Tools and Infrastructure, Server Graphical Shell	Graphical Management Tools and Infrastructure, Server Graphical Shell, Desktop Experience
Or, run the Windows PowerShell install/uninstall commands with these values for the Name parameter:	none	`Server-Gui-Mgmt-Infra`	`Server-Gui-Mgmt-Infra, Server-Gui-Shell`	`Server-Gui-Mgmt-Infra, Server-Gui-Shell, Desktop-Experience`

Features on Demand

In previous versions of Windows, even if a server role or feature was disabled, the binary files for it were still present on the disk, consuming space. In Windows Server 2012, not only can you disable a role or feature, but you can also completely remove its files, a state shown as “removed” in Server Manager or “disabled with payload removed” in Dism.exe. To reinstall a role or feature that been completely removed, you must have access to an installation source.

To completely remove a role or feature, use `-Remove` with the `Uninstall-WindowsFeature` cmdlet of Windows PowerShell. For example, to completely remove Windows Explorer, Internet Explorer, and dependent components, run the following Windows PowerShell command:

```
Uninstall-WindowsFeature Server-Gui-Shell -Remove
```

To install a role or feature that has been completely removed, use the Windows PowerShell `-Source` option of the `Install-WindowsFeature` Server Manager cmdlet. The `-Source` option specifies a path to a WIM image and the index number of the image. If you do not specify a `-Source` option, Windows will use Windows Update by default. Offline VHDs cannot be used as a source for installing roles or features which have been completely removed.

Only component sources from the exact same version of Windows are supported. For example, a component source derived from the Windows Server Developer Preview is not a valid installation source for a server running Windows Server 2012.

To install a removed role or feature using a WIM image, use the steps and Windows PowerShell cmdlets:

1. Run `Get-windowsimage –imagepath <path to wim>\install.wim`, and make note of the index of the Windows Server 2012 image.
2. `Install-WindowsFeature <featurename> -Source wim:<path>:<index>`, where:

   Featurename is the name of the role or feature from Get-WindowsFeature

   Path is the path to the WIM mount point

   Index is the index of the server image from Step 1.

For example: `Install-WindowsFeature <featurename> -Source wim:d:\sources\install.wim:4`

You can also specify a source for servers that are domain members using Group Policy. Navigate to **Computer Configuration > Administrative Templates > System > "Specify settings for optional component installation and component repair"**

Note

Permissions might affect the system's ability to access Windows features for installation over a network. The Trusted Installer process runs within the machine account. If you encounter network access issues, try issuing a net use command (for example, **net use * \\path\to\network** or the cmdlet `New-PSDrive -Name Z -PSProvider Filesystem -Root "\\path\to\network`) to mount the network source and then copy the source locally. Then use the local copy as the installation source.

Practical applications

These examples give you an idea of how you can choose the installation option that might be most appropriate for your deployment needs:

- Server Core installations require approximately 4 GB less space than a Server with a GUI installation. By using Server Core installations on virtual machines, you can achieve a significant space savings by not having to store the GUI files on the virtual machine's disk.
- Servers often have comparatively large amounts of memory and complex disk arrays, both of which can take a significant amount of time to initialize at startup. Because Server Core installations minimize the number of restarts required for updates, the frequency at which disk arrays and memory must be re-initialized is reduced.
- Certain server applications have dependencies on certain Windows services, libraries, applications, and files that are not available in Server Core installations, but the administrator

wants to take advantage of the reduced need for updating typical of Server Core installations. The Minimal Server Interface offers additional compatibility while still maintaining a reduced system footprint (though to a lesser extent than a Server Core installation).

- Features on Demand can be used to reduce the footprint for your virtual machine deployments by removing roles and features that will never be deployed in your virtual machines. Depending on the roles and features used in your virtual machines, it is possible to reduce the size by over 1 GB.

Reference table

This table summarizes which features are available locally depending on which installation option you choose.

	Server Core installation option	**Minimal Server Interface**	**Server with a GUI installation option**	**Desktop Experience feature installed**
Command prompt	available	available	available	available
Windows PowerShell/Microsoft .NET	available	available	available	available

1.4

Server Core and Full Server Integration Overview

In Windows Server 2012, the Server Core installation option is no longer an irrevocable selection that is made during setup. In Windows Server 2008 R2 and Windows Server 2008, if your requirements changed, there was no way to convert to a full installation or a Server Core installation without completely reinstalling the operating system. An administrator now has the ability to convert between a Server Core installation and a full installation as needed.

There are several scenarios in which this capability is especially useful:

- An administrator installed and is running a full installation option of Windows Server 2012, but exclusively using the roles that run on a Server Core installation. The administrator can convert the servers to Server Core installations to reduce the image size and increase servicing advantages without having to reprovision all of their servers.
- An administrator installs a Server Core installation and now needs to make a change or troubleshoot something that is not possible with the remote GUI. The administrator may not know how to make the change from the command line or cannot find a command-line equivalent. The administrator can convert the server to a full installation, perform the changes, and then convert it back to a Server Core installation to reduce the image size and maintain servicing advantages.
- An administrator wants to use the GUI for all of the initial configuration steps to make the initial configuration experience as easy as possible, yet wants to reduce the image size and maintain the servicing advantages that a Server Core installation provides. The administrator can install a full installation, configure the server as needed, and then convert it to a Server Core installation.
- An enterprise mandates a single server operating system image, so it cannot use a Server Core installation because it requires two images. Windows Server 2012 integrates the Server

Core installation and the full server installation options. Now the enterprise can use a single server operating system image to deploy full installations of Windows Server 2012 and then convert them to Server Core installations to reduce the image size and provide the servicing advantages that it offers.

Requirements

You need a Server Core installation or a full installation of Windows Server 2012. No special hardware is required.

Technical overview

In Windows Server 2008 R2 and Windows Server 2008, the Server Core installation and the full installation options were selections that an administrator made at the time of installation.

Figure 1 Earlier Windows Server installations

In Windows Server 2012, the installation options are integrated, and three large optional features are provided. An administrator can install or uninstall these options to move between Server Core and full server installations.

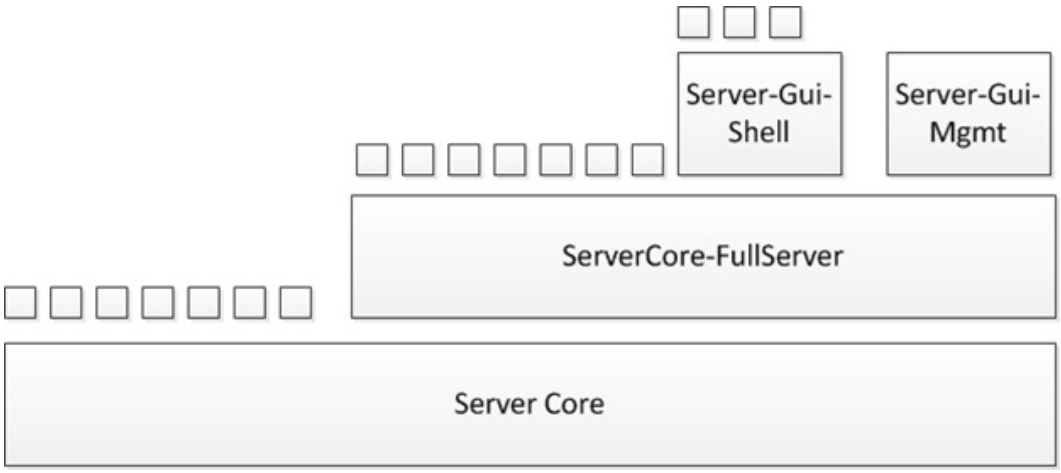

Figure 2 Windows Server 2012 installation options

Configure and Manage Server Core Installations

Because when Windows Server® 2012 is in Server Core mode, the help system and browser are not available, this collection of topics provides the information needed to install and deploy Server Core servers; install, manage, and uninstall server roles and features; configure settings such as server activation and naming, domain membership, and Windows Firewall; installing updates; and managing the server locally or remotely. It also includes a quick reference table of common tasks and the commands for accomplishing them locally on a Server Core server.

If you choose the Server Core option, the standard user interface (the “Server Graphical Shell”) is not installed; you manage the server using remote user interface tools, Windows PowerShell, or, if necessary, locally using the command line (or Windows PowerShell). For more information about the differences between Server Core and Server with a GUI, the features included in each mode, switching between the modes, the Minimal Server Interface mode, and Features on Demand, see http://technet.microsoft.com/library/hh831786.

- Deploy a Server Core Server

- Install Server Roles and Features on a Server Core Server
- Manage a Server Core Server
- Service Updates on a Server Core Server
- Quick Reference for Server Core Tasks

Deploy a Server Core Server

This topic addresses basic information concerning installation and deployment of Windows Server® 2012 in Server Core mode.

When you install Windows Server 2012, you can choose between **Server Core Installation** and **Server with a GUI**. The “Server with a GUI” option is the Windows Server 2012 equivalent of the Full installation option available in Windows Server 2008 R2. The “Server Core Installation” option reduces the space required on disk, the potential attack surface, and especially the requirements for servicing and restarting the server, so we recommend that you choose the Server Core installation unless you have a particular need for the additional user interface elements and graphical management tools that are included in the “Server with a GUI” option. For this reason, the Server Core installation is now the default. Because you can freely switch between these options at any time later, one approach might be to initially install the Server with a GUI option, use the graphical tools to configure the server, and then later switch to the Server Core Installation option.

If you choose the Server Core option, the standard user interface (the “Server Graphical Shell”) is not installed; you manage the server using remote user interface tools, Windows PowerShell, or,

if necessary, locally using the command line (or Windows PowerShell). For more information about the differences between Server Core and Server with a GUI, the features included in each mode, switching between the modes, the Minimal Server Interface mode, and Features on Demand, see http://technet.microsoft.com/library/hh831786.

Initial installation

At the time you run Setup, you have the option to install the server in Server Core mode or Server with a GUI mode.

Using Setup to install the server directly in Server Core mode

1. Insert the appropriate Windows Server 2012 installation media into your DVD drive.
2. When the auto-run dialog box appears, click **Install Now**.
3. Follow the instructions on the screen to complete Setup.
4. You will be prompted to set a password for the Administrator account.

Using an unattend file to install the server directly in Server Core mode

Using an unattend file to install directly in Server Core mode enables you to perform most of the initial configuration tasks during Setup.

To install directly in Server Core mode with an unattend file

1. Create a .xml file titled Unattend.xml by using a text editor or Windows System Image Manager.
2. Copy the Unattend.xml file to a local drive or shared network resource.
3. Boot your computer to Windows Preinstallation Environment (Windows PE).
4. Insert the media disk with the Server Core installation of Windows Server 2012 into your disk drive. If the auto-run Setup window appears, click **Cancel**.
5. Change to the drive that contains the installation media.
6. Run **setup /unattend:<path>\unattend.xml**, where *path* is the path to the Unattend.xml file.
7. Allow Setup to complete.

Configure a Server Core Server

This topic explains how to accomplish common server configuration tasks, such as setting passwords, configuring Windows Firewall, joining a domain, and activating the server, all while the server is in Server Core mode.

This topic assumes that you have installed the server in Server Core mode initially and are proceeding directly to these configuration tasks. If you have installed the server in Server with a GUI mode and have since switched to Server Core mode, these steps still apply.

Note
If you close all command prompts, you will have no way to manage the server in Server Core mode. To recover, you can press CTRL+ALT+DELETE, click Start Task Manager, click File, click Start New Task, and then type cmd.exe. Alternatively, you can log off and log back on again.

Note
Because there is no Web browser in Server Core mode, you cannot access the Internet or activate the product through a proxy server that requires users to log on. If you have a proxy server that requires users to log on, you can switch the server to Server with a GUI mode, activate the server, and then switch back to Server Core mode.

Task	Description
1.1. Set the administrative password	Set the administrative password
1.2. Set a static IP address	Set a static IP address
1.3 Join a domain	Join a domain
1.4 Rename the server	Rename the server
1.5 Activate the server	Activate the server
1.6 Configure Windows Firewall	Configure Windows Firewall
1.7. Enable Windows PowerShell remoting	Enable remote use of Windows PowerShell

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

1.1. Set the administrative password

To set the administrative password

1. When your computer starts for the first time after the installation completes, you will be

prompted to enter a new password.

2. Type an appropriate administrative password.

You can later change the administrative password. To do this, log in and press CTRL+ALT+DELETE, and then choose **Change Password** from the Windows Security menu.

1.2. Set a static IP address

Note

A DHCP address is provided by default. You should perform this procedure only if you need a static IP address.

To view your current network configuration use the `Get-NetIPConfiguration` Windows PowerShell cmdlet.

To view the IP addresses you are already using, use the `Get-NetIPAddress` Windows PowerShell cmdlet.

For a complete reference on Windows PowerShell cmdlets for Net TCP/IP, see http://technet.microsoft.com/en-us/library/hh826150.aspx.

To set a static IP address

1. In Windows PowerShell, run `Get-NetIPInterface`.
2. Make a note of the number shown in the **IfIndex** column of the output for your IP interface or the **InterfaceDescription** string. If your computer has more than one network adapter, make a note of the number or string corresponding to the interface for which you wish to set a static IP address.
3. In Windows PowerShell, run `New-NetIPAddress –InterfaceIndex 12 –IPAddress -192.0.2.2 –PrefixLength 24 –DefaultGateway -192.0.2.1`

   Where:

   `InterfaceIndex` is the value of **IfIndex** from Step 2 (in this example, 12)

   `IPAddress` is the static IP address you intend to set (in this example, 192.0.2.2)

   `PrefixLength` is the prefix length (another form of subnet mask) for the IP address you intend to set (in this example, 24)

   `DefaultGateway` is the default gateway (in this example, 192.0.2.1)
4. In Windows PowerShell, run `Set-DNSClientServerAddress –InterfaceIndex 12 -ServerAddresses 192.0.2.4`

   Where:

   `InterfaceIndex` is the value of **IfIndex** from Step 2

   `ServerAddresses` is the IP address of your DNS server
5. To add multiple DNS servers, run `Set-DNSClientServerAddress –InterfaceIndex 12 -ServerAddresses 192.0.2.4,192.0.2.5`

   Where in this example, 192.0.2.4, 192.0.2.5 are both IP addresses of DNS servers

If you need to switch to using DHCP, use the Windows PowerShell command `Set-DnsClientServerAddress –InterfaceIndex 12 –ResetServerAddresses`.

1.3 Join a domain

To join a domain

1. In Windows PowerShell, run `Add-Computer`. You will be prompted for both credentials to join the domain and the domain name.
2. If you need to add a domain user account to the local Administrators group, either use the Windows PowerShell cmdlets documented at http://technet.microsoft.com/en-us/library/hh826150.aspx, or at a command prompt, run the following command:

   net localgroup administrators /add <DomainName>\<UserName>
3. Restart the computer. You can do this in Windows PowerShell with the command `Restart-Computer`.

1.4 Rename the server

To rename the server

1. Determine the current name of the server with the **hostname** or **ipconfig** command.
2. In Windows PowerShell, run `Rename-Computer`.
3. Restart the computer.

1.5 Activate the server

In Windows PowerShell, run `slmgr.vbs –ipk<productkey>`. Then run `slmgr.vbs –ato`. If activation is successful, no message will return.

Note

You can also activate the server by phone, using a Key Management Service (KMS) server, or remotely. To activate remotely, from a computer that is running Windows Vista, Windows 7, Windows Server 2008, Windows Server 2008 R2, Windows® 8, or Windows Server 2012, use Windows PowerShell to run `cscript windows\system32\slmgr.vbs <ServerName> <UserName> <password>:-ato`.

1.6 Configure Windows Firewall

You can configure Windows Firewall locally on the Server Core computer using Windows PowerShell cmdlets and scripts. See http://technet.microsoft.com/library/hh831755.aspx for documentation of basic Windows Firewall tasks using Windows PowerShell.

1.7. Enable Windows PowerShell remoting

You can enable Windows PowerShell Remoting, in which commands typed in Windows PowerShell on one computer run on another computer. Enable Windows PowerShell Remoting with `Enable-PSRemoting`.

For more information, see http://go.microsoft.com/fwlink/?LinkID=135183

Configure a Server Core Server with Sconfig.cmd

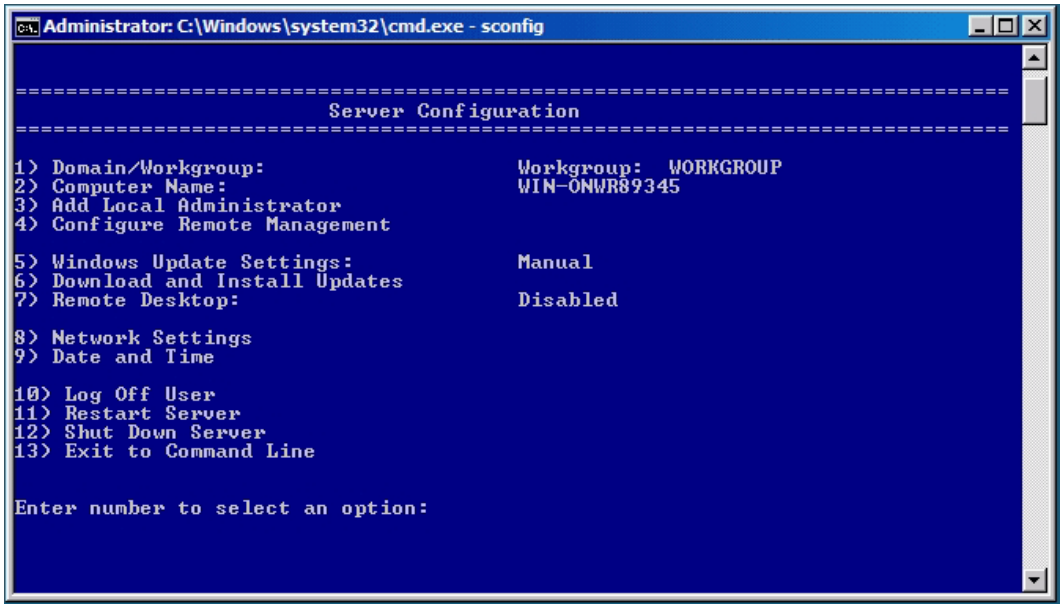
In Windows Server 2012, you can use the Server Configuration tool (Sconfig.cmd) to configure and manage several common aspects of Server Core installations. You must be a member of the Administrators group to use the tool.

Sconfig.cmd is available in the Minimal Server Interface and in Server with a GUI mode.

To start the Server Configuration Tool

1. Change to the system drive.
2. Type **Sconfig.cmd**, and then press ENTER. The Server Configuration tool interface opens:

Screenshot of Sconfig.cmd user interface



Domain/Workgroup settings

The current Domain/Workgroup settings are displayed in the default Server Configuration tool screen. You can join a domain or a workgroup by accessing the **Domain/Workgroup** settings page from the main menu and following the instructions on the following pages, supplying any required information.

If a domain user has not been added to the local administrators group, you will not be able to make system changes, such as changing the computer name, by using the domain user. To add a domain user to the local administrators group, allow the computer to restart. Next, log on to the computer as the local administrator and follow the steps in the **Local administrator settings** section later in this document.

Note

You are required to restart the server to apply any changes to domain or workgroup membership. However, you can make additional changes and restart the server after all of the changes to avoid the need to restart the server multiple times. By default, running virtual machines are automatically saved prior to restarting the Hyper-V Server.

Computer name settings

The current computer name is displayed in the default Server Configuration Tool screen. You can change the computer name by accessing the “Computer Name” settings page from the main menu and following the instructions.

Note

You are required to restart the server to apply any changes to domain or workgroup membership. However, you can make additional changes and restart the server after all of the changes to avoid the need to restart the server multiple times. By default, running virtual machines are automatically saved prior to restarting the Hyper-V Server.

Local administrator settings

To add additional users to the local administrators group, use the **Add Local Administrator** option on the main menu. On a domain joined machine, enter the user in the following format: domain\username. On a non-domain joined machine (workgroup machine), enter only the user name. The changes take effect immediately.

Network settings

You can configure the IP address to be assigned automatically by a DHCP Server or you can assign a static IP address manually. This option allows you to configure DNS Server settings for the server as well.

Note
These options and many more are now available using the Networking Windows PowerShell cmdlets. For more information, see Network Adapter Cmdlets in the Windows Server Library.

Windows Update settings

The current Windows Update settings are displayed in the default Server Configuration Tool screen. You can configure the server to use Automatic or Manual updates on the **Windows Update Settings** configuration option on the main menu.

When **Automatic Updates** are selected, the system will check for and install updates every day at 3:00 AM. The settings take effect immediately. When **Manual** updates are selected, the system will not check for updates automatically.

At any time, you can download and install applicable updates from the **Download and Install Updates** option on the main menu.

Remote Desktop settings

The current status of remote desktop settings is displayed in the default Server Configuration Tool screen. You can configure the following Remote Desktop settings by accessing the **Remote Desktop** main menu option and following the instructions on screen.

- enable Remote Desktop for Clients running Remote Desktop with Network Level Authentication
- enable Remote Desktop for clients running any version of Remote Desktop
- disable Remote

Date and time settings

You can access and change date and time settings by accessing the **Date and Time** main menu option

To enable remote management

You can enable various remote management scenarios from the **Configure Remote Management** main menu option:

- Microsoft Management Console remote management
- Windows PowerShell
- Server Manager

To log off, restart, or shut down the server

To log off, restart, or shut down the server, access the corresponding menu item from the main menu. These options are also available from the Windows Security menu which can be accessed from any application at any time by pressing CTRL+ALT+DEL.

To exit to the command line

Select the **Exit to the Command Line** option and press ENTER to exit to the command line. To return to the Server Configuration Tool, type **Sconfig.cmd**, and then press ENTER

Install Server Roles and Features on a Server Core Server

When Windows Server 2012 is in Server Core mode, the following server roles are supported:

- Active Directory Certificate Services
- Active Directory Domain Services
- DHCP Server
- DNS Server
- File Services (including File Server Resource Manager)
- Active Directory Lightweight Directory Services (AD LDS)
- Hyper-V
- Print and Document Services
- Streaming Media Services
- Web Server (including a subset of ASP.NET)
- Windows Server Update Server
- Active Directory Rights Management Server

- Routing and Remote Access Server, including the following sub-roles:
  - Remote Desktop Services Connection Broker
  - Licensing
  - Virtualization

When Windows Server 2012 is in Server Core mode, the following server features are supported:

- Microsoft .NET Framework 3.5
- Microsoft .NET Framework 4.5
- Windows PowerShell
- Background Intelligent Transfer Service (BITS)
- BitLocker Drive Encryption
- BitLocker Network Unlock
- BranchCache
- Data Center Bridging
- Enhanced Storage
- Failover Clustering
- Multipath I/O
- Network Load Balancing
- Peer Name Resolution Protocol
- Quality Windows Audio Video Experience
- Remote Differential Compression
- Simple TCP/IP Services
- RPC over HTTP Proxy
- SMTP Server
- SNMP Service
- Telnet client
- Telnet server
- TFTP client
- Windows Internal Database
- Windows PowerShell Web Access
- Windows Process Activation Service
- Windows Standards-based Storage Management
- WinRM IIS extension
- WINS server
- WoW64 support

Note

This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

Installing and uninstalling server roles and features

To discover the server roles and features on your computer, run the Windows PowerShell cmdlet `Get-WindowsFeature`.

To install a server role or feature, make a note of the role or feature name in the output from `Get-WindowsFeature` and then run `Install-WindowsFeature <featurename>`.

You can install (or uninstall) more than one feature at a time by separating feature names with commas. For example, to install both Server Graphical Shell and Windows PowerShell ISE (and its dependencies), if you run `Install-WindowsFeature Server-Gui-Shell,PowerShell-ISE`, the server is converted to Server with a GUI mode.

Appending the `-WhatIf` parameter to either `Install-WindowsFeature <featurename>` or `Uninstall-WindowsFeature <featurename>` displays any dependent features that will be installed or uninstalled along with the feature you have specified.

To uninstall a server role or feature, run the Windows PowerShell cmdlet `Uninstall-WindowsFeature <featurename>`

Note

When you uninstall a role or feature with this command, the binary files for it remain on the disk. This allows you to add the role or feature later without having to access an installation source (such as an installation DVD or WIM image). To completely remove the files for the role or feature from the disk or to reinstall a role or feature that has been completely removed, see “Working with Features on Demand” in this topic.

Working with Features on Demand

In previous versions of Windows, even if a server role or feature was disabled, the binary files for it were still present on the disk, consuming space. In Windows Server 2012, not only can you disable a role or feature, but you can also completely remove its files, a state shown as “removed” in Server Manager or “disabled with payload removed” in Dism.exe. To reinstall a role or feature that has been completely removed, you must have access to an installation source.

To completely remove a role or feature, use `-Remove` with the `Uninstall-WindowsFeature` cmdlet of Windows PowerShell. For example, to completely remove Windows Explorer, Internet Explorer, and dependent components, run the following Windows PowerShell command:

```
Uninstall-WindowsFeature Server-Gui-Shell -remove
```

To install a role or feature that has been completely removed, use the Windows PowerShell `-Source` option of the `Install-WindowsFeature` Server Manager cmdlet. The `-Source` option specifies a path to a WIM image and the index number of the image. If you do not specify a `-Source` option, Windows will use Windows Update by default.

To install a removed role or feature using a WIM image, use these steps and Windows PowerShell cmdlets:

1. Run `Get-windowsimage –imagepath <path to wim>\install.wim`, and make note of the index of the image for the Server with a GUI version of Windows Server 2012.
2. `Install-WindowsFeature <featurename> -Source wim:<path>:<index>`, where:

   Featurename is the name of the role or feature from Get-WindowsFeature

   Path is the path to the WIM mount point

   Index is the index of the server image from Step 1.

For example, if the Server with a GUI image is in D:\sources: `Install-WindowsFeature <featurename> -Source wim:d:\sources\install.wim:4`

You can also specify a source for servers that are domain members using Group Policy. Navigate to **Computer Configuration > Administrative Templates > System > "Specify settings for optional component installation and component repair"**

Note

Permissions might affect the system's ability to access Windows features for installation over a network. The Trusted Installer process runs within the machine account. If you encounter network access issues, try issuing a net use command (for example, **net use * \\path\to\network**) to connect to the network source and then copy the source locally. Then use the local copy as the installation source.

Manage a Server Core Server

This topic explains the various methods available for managing a Windows Server 2012 server in Server Core mode, as well as how to add hardware and manage drivers. You can manage the server in the following ways:

- Locally and remotely using Windows PowerShell
- Remotely using Server Manager
- Remotely using an MMC snap-in
- Remotely with Remote Desktop Services
- Converting the server to Server with a GUI mode

Task	Description
1.1. Manage with Windows PowerShell	You can manage servers in Server Core mode using Windows PowerShell either locally or remotely.
1.2 Manage with Server Manager	By running Server Manager on a remote computer, you can connect to a server that is in Server Core mode.
1.3 Manage with Microsoft Management Console	By using a Microsoft Management Console (MMC) snap-in, you can connect to a server that is in Server Core mode.
1.4 Manage with Remote Desktop Services	By using another computer running Windows, you can use Remote Desktop Services to run scripts and tools on a server that is in Server Core mode.
1.5 Switch to Server with a GUI mode	You can switch the computer to Server with a GUI mode, use the usual user interface tools to accomplish your tasks, and then switch back to Server Core mode.
1.6 Add hardware and manage drivers locally	You can add hardware and manage drivers locally while in Server Core mode.

There are some important limitations and tips to keep in mind when you work with a server in Server Core mode:

- If you close all command prompt windows and want to open a new Command Prompt window, press CTRL+ALT+DELETE, click **Start Task Manager**, click **More Details**, click **File**, click **Run**, and then type **cmd.exe**. Alternatively, you can log off and log back on.
- If you close all Windows PowerShell windows and want to open a new one, press CTRL+ALT+DELETE, open Task Manager, click **More Details**. The File menu opens. In the **File** menu, click **Run new task**, and then start either Cmd.exe or Powershell.exe.
- Any command or tool that attempts to start Windows Explorer will not work. For example, **start .** used from a command prompt will not work.
- There is no support for HTML rendering or HTML help in Server Core mode.
- When in Server Core mode, there are no notifications for activation, new updates, or password expiration because these notifications require the Windows Explorer shell, which is not present in Server Core mode.
- If you need to write a script for managing a server in Server Core mode that requires the secure inclusion of an administrative password, see the scripting column on Microsoft TechNet (http://go.microsoft.com/fwlink/?LinkID=56421).
- Server Core mode supports Windows Installer in quiet mode so that you can install tools and utilities from Windows Installer files.

- When installing Windows Installer packages on a server in Server Core mode, use the **/qb** option to display the basic user interface.
- To change the time zone while in Server Core mode, run `Set-Date`.
- To change international settings while in Server Core mode, run **control intl.cpl**.
- Control.exe will not run on its own. You must run it with either Timedate.cpl or Intl.cpl.
- Winver.exe is not available in Server Core mode. To obtain version information use Systeminfo.exe.

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

1.1. Manage with Windows PowerShell

You can accomplish most management tasks locally or from a remote computer by using Windows PowerShell cmdlets and scripts. To start Windows PowerShell, run **powershell** in a command prompt.

To run Windows PowerShell remotely, see 1.7. Enable Windows PowerShell remoting

For more information about working with Windows PowerShell, see http://technet.microsoft.com/library/hh857343.aspx.

1.2 Manage with Server Manager

Server Manager is a management console in Windows Server® 2012 that helps IT professionals provision and manage both local and remote Windows-based servers from their desktops, without requiring either physical access to servers, or the need to enable Remote Desktop protocol (RDP) connections to each server. Although Server Manager is available in Windows Server 2008 R2 and Windows Server 2008, Server Manager has been completely redesigned for Windows Server 2012, to support remote, multi-server management, and help increase the number of servers an administrator can manage.

Note
You must use the version of Server Manager in Windows Server 2012 or that is available as part of the Remote Server Administration Tools for Windows 8 download package. Older versions of Server Manager will not work.

To enable your local server to be managed by Server Manager running on a remote server, run the Windows PowerShell cmdlet `Configure-SMRemoting.exe -Enable`.

1.3 Manage with Microsoft Management Console

Many snap-ins for Microsoft Management Console (MMC) can be use remotely to manage your Server Core server.

To manage a server in Server Core mode that is a domain member with an MMC snap-in

1. Start an MMC snap-in, such as **Computer Management**.
2. In the left pane, right-click the top of the tree and click **Connect to another computer**. (In the Computer Management example, you would right-click **Computer Management (Local)**.)
3. In **Another computer**, type the computer name of the server that is in Server Core mode and click **OK**. You can now use the MMC snap-in to manage the Server Core server as you would any other computer running a Windows Server operating system.

To manage a server in Server Core mode that is not a domain member with an MMC snap-in

1. If the Server Core server is not a member of a domain, establish alternate credentials to use to connect to the Server Core computer by typing the following command at a command prompt on the remote computer:

   cmdkey /add:<ServerName> /user:<UserName> /pass:<password>

   Where:

   ServerName is the name of the Server Core server

   UserName is the name of an administrator account

   To be prompted for a password, omit the **/pass** option.
2. When prompted, type the password for the user name that is specified in the previous step.
3. If the firewall on the Server Core server is not already configured to allow MMC snap-ins to connect, follow the steps in "To configure Windows Firewall to allow MMC snap-in(s) to connect." Then return to this procedure.
4. On a different computer, start an MMC snap-in, such as Computer Management.
5. In the left pane, right-click the top of the tree and click **Connect to another computer**. (In the Computer Management example, you would right-click **Computer Management (Local)**.)
6. In **Another computer**, type the computer name of the server that is in Server Core mode and click **OK**. You can now use the MMC snap-in to manage the Server Core server as you would any other computer running a Windows Server operating system.

To configure Windows Firewall to allow MMC snap-in(s) to connect

- To allow all MMC snap-ins to connect, run

  ```
  Enable-NetFirewallRule -DisplayGroup "Remote Administration"
  ```
- To allow only specific MMC snap-ins to connect, run:

  ```
  Enable-NetFirewallRule -DisplayGroup "<rulegroup>"
  ```

  Where:

  Rulegroup is one of the values from the table below, depending on which snap-in you

want to connect.

MMC snap-in	Rule group
Event Viewer	Remote Event Log Management
Services	Remote Service Management
Shared Folders	File and Printer Sharing
Task Scheduler	• Performance Logs and Alerts • File and Printer Sharing
Disk Management	Remote Volume Management
Windows Firewall with Advanced Security	Windows Firewall Remote Management

Notes

Some MMC snap-ins do not have a corresponding rule group that allows them to connect through the firewall. However, enabling the rule groups for Event Viewer, Services, or Shared Folders will allow most other snap-ins to connect. Additionally, certain snap-ins require further configuration before they can connect through Windows Firewall:

- **Disk Management.** You must first start the Virtual Disk Service (VDS) on the Server Core computer. You must also configure the Disk Management rules appropriately on the computer that is running the MMC snap-in.
- **IP Security Monitor.** You must first enable remote management of this snap-in. To do this, at a command prompt, type:

  Cscript \windows\system32\scregedit.wsf /im 1
- **Reliability and Performance.** The snap-in does not require any further configuration, but when you use it to monitor a Server Core computer, you can only monitor performance data. Reliability data is not available.

1.4 Manage with Remote Desktop Services

You can use Remote Desktop to manage a server in Server Core mode from remote computers by using Remote Desktop Services.

To manage a Server Core server using Remote Desktop

1. On the Server Core server, run:

   cscript C:\Windows\System32\Scregedit.wsf /ar 0

   This enables the Remote Desktop for Administration mode to accept connections.
2. On another computer, click **Start**, click **Run**, type **mstsc**, and then click **OK**.
3. In **Computer**, enter the name of the server that is in Server Core mode, and click **Connect**.

4. Log on using an administrator account.
5. When the command prompt appears, you can manage the computer using the Windows command-line tools.
6. When you have finished remotely managing the Server Core computer, type **logoff** in the command prompt to end your Remote Desktop session

Note

If you are running the Remote Desktop Services client on a previous version of Windows, you must turn off the higher security level that is set by default in Windows Server 2012. To do this, after step 1, type the following command at the command prompt:**cscript C:\Windows\System32\Scregedit.wsf /cs 0**

1.5 Switch to Server with a GUI mode

There may be situations in which you need to use the graphical user interfaces available in Server with a GUI mode. You can switch the system to Server with a GUI mode by following the steps below, although a restart is required. For more information about the differences between Server Core mode and Server with a GUI mode, as well as information about the Minimal Server Interface and Features on demand, see Windows Server Installation Options.

To convert from Server Core mode to Server with a GUI mode when the server was initially installed in Server with a GUI mode

- Run `Install-WindowsFeature Server-Gui-Mgmt-Infra,Server-Gui-Shell -Restart`

To convert from Server Core mode to Server with a GUI mode when the server was initially installed in Server Core mode

1. Determine the index number for a Server with a GUI image (for example, **SERVERDATACENTER**, not **SERVERDATACENTERCORE**) using this cmdlet: `Get-WindowsImage -ImagePath <path to wim>\install.wim`
2. Run `Install-WindowsFeature Server-Gui-Mgmt-Infra, Server-Gui-Shell -Restart -Source wim:<path to wim>\install.wim:<Index # from step 1>`
3. Alternatively, if you want to use Windows Update as the source instead of a WIM file, use this Windows PowerShell cmdlet:

   ```
   Install-WindowsFeature Server-Gui-Mgmt-Infra,Server-Gui-Shell -Restart
   ```

After you have accomplished the management tasks, you can switch the server back to Server Core mode whenever it is convenient (a restart is required) with the Windows PowerShell cmdlet

```
Uninstall-WindowsFeature Server-Gui-Mgmt-Infra -restart
```

1.6 Add hardware and manage drivers locally

To add hardware to a server in Server Core mode

1. Follow the instructions provided by the hardware vendor for installing new hardware:
   - If the driver for the hardware is included in Windows Server 2012, Plug and Play will start and install the driver.
   - If the driver for the hardware is not included, proceed with the steps 2 and 3.
2. Copy the driver files to a temporary folder on the server running a Server Core installation.
3. At a command prompt, open the folder where the driver files are located, and then run the following command:

   pnputil –i –a <driverinf>

   Where:

   driverinf is the file name of the .inf file for the driver.
4. If prompted, restart the computer.

To obtain a list of drivers that are installed

- At a command prompt, run

  sc query type= driver

Note

You must include the space after the equal sign for the command to complete successfully.

To disable a device driver

- At a command prompt, run

  sc delete <service_name>

  Where:

  service_name is the name of the service that you obtain by running **sc query type= driver**

Service Updates on a Server Core Server

This topic discusses the various ways you can keep a Server Core server up to date with updates. You can service updates in the following ways:

- **Using Windows Update automatically or with WSUS.** By using Windows Update, either automatically or with command-line tools, or Windows Server Update Services (WSUS), you can service servers running a Server Core installation.
- **Manually.** Even in organizations that do not use Windows update or WSUS, you can apply updates manually.

Task	Description
1.1. Manage updates automatically with Windows Update	Managing updates automatically with Windows Update
1.2. Manage updates with WSUS	Managing updates with Windows Server Update Services
1.3. Manage updates manually	Managing updates manually

Note

This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

1.1. Manage updates automatically with Windows Update

To verify the current Windows Update setting, at a command prompt, run the following command:

Cscript scregedit.wsf /AU /v

To enable automatic updates, run the following commands:

Net stop wsuaserv

cscript scregedit.wst /AU 4

net start wsuaserv

To disable automatic updates, run the following commands:

Net stop wsuaserv

cscript scregedit.wsf /AU 1

net start wsuaserv

If the server is a member of a domain, you can also configure Windows Update using Group Policy. For more information, see http://go.microsoft.com/fwlink/?LinkId=192470. However, when you use this method, only option 4 ("Auto download and schedule the install") is relevant to Server Core installations because of the lack of a graphical interface. For more control over which updates are installed and when, you can use a script which provides a command-line equivalent of most of the Windows Update graphical interface. For information about the script, see http://go.microsoft.com/fwlink/?LinkId=192471.

To force Windows Update to immediately detect and install any available updates, run the following command:

wuauclt /detectnow

Depending on the updates that are installed, you might need to restart the computer, although the system will not notify you of this. To determine if the installation process has completed, use Task Manager to verify that the **Wuauclt** or **Trusted Installer** processes are not actively running. You can also use the methods in the "Viewing installed updates" section to check the list of installed updates.

1.2. Manage updates with WSUS

If the Server Core server is a member of a domain, you can configure it to use a WSUS server with Group Policy. For more information, see http://go.microsoft.com/fwlink/?LinkId=192472.

If the server is not a member of a domain, edit the Registry to configure it to use a WSUS server. For more information, see http://go.microsoft.com/fwlink/?LinkId=192473.

Whenever you configure WSUS settings, be sure to select options that are valid for Server Core installations. For example, since there is no graphical interface, there is no way to receive WSUS notifications. For more control over which updates are installed and when, you can use a script which provides a command-line equivalent of most of the Windows Update graphical interface. For information about the script, see http://go.microsoft.com/fwlink/?LinkId=192471.

1.3. Manage updates manually

To install an update manually, download the update and make it available to the Server Core computer, and then run the following command:

Wusa <update>.msu /quiet

Note

Depending on the updates that are installed, you may need to restart the computer, although the system will not notify you of this.

To uninstall an update manually, download the update and make it available to the Server Core computer, and then run the following command:

Wusa /uninstall <update>.msu /quiet

Note
Depending on the updates that are installed, you may need to restart the computer, although the system will not notify you of this.

To view installed updates, run either of these commands:

systeminfo

wmic qfe list

Quick Reference for Server Core Tasks

This topic is a collection of common administrative tasks for Server Core servers that you can perform locally or remotely from a command prompt.

Whenever possible, Windows PowerShell commands are used and are styled thus: `Get-NetIPConfiguration`. When no Windows PowerShell equivalent is available, run the indicated command at an ordinary command prompt or a Windows PowerShell prompt. These command are styled thus: **Netdom remove**

Task	Description
1.1. Configuration and installation	Configuration and installation
1.2. Networking and firewall	Networking and firewall
1.3. Updates and error reporting	Updates and error reporting
1.4. Services, processes, and performance	Services, processes, and performance
1.5. Event logs	Event logs
1.6. Disk and file system	Disk and file system
1.7. Hardware	Hardware

Note
This topic includes sample Windows PowerShell cmdlets that you can use to automate some of the procedures described. For more information, see Using Cmdlets.

1.1. Configuration and installation

Task	Steps
Set the local administrative password	Run: **Net user administrator ***
Join a computer to a domain	Run `Add-Computer` For more information see Configure a Server Core Server
Confirm that the domain has changed	Run: **set**
Remove a computer from a domain	Run: `Remove-Computer`
Add a user to the local Administrators group.	Run: **net localgroup Administrators /add <domain>\<username>**
Remove a user from the local Administrators group	Run: **net localgroup Administrators /delete <domain\username>**
Add a user to the local computer	Run: **net user <domain\user name> /add ***
Add a group to the local computer	Run: **net localgroup <group name> /add**
Change the name of a domain-joined computer	Run `Rename-Computer`
Confirm the new computer name	Run: **set c**
Change the name of a computer in a work group	Run: `Rename-Computer`

Task	Steps
Disable paging file management	Run: **wmic computersystem where name="<computername>" set AutomaticManagedPagefile=False**
Configure the paging file	Run: **wmic pagefileset where name="<path/filename>" set InitialSize=<initialsize>,MaximumSize=<maxsize>** Where: *path/filename* is the path to and name of the paging file *initialsize* is the starting size of the paging file in bytes *maxsize* is the maximum size of the paging file in bytes
Change to a static IP address	See http://technet.microsoft.com/library/hh826123.
Set a static DNS address	See http://technet.microsoft.com/library/hh826123.
Change to a DHCP-provided IP address from a static IP address	See http://technet.microsoft.com/library/hh826123.
Enter a product key	Run `slmgr.vbs -ipk <product key>`, and then run `slmgr.vbs -ato`. For more information, see Configure a Server Core Server.
Activate the server locally	Run **slmgr.vbs -ato**
Activate the server remotely	1. Run **cscript slmgr.vbs –ipk <product key><server name><username><password>** 2. Run **cscript slmgr.vbs -ato <servername> <username> <password>** 3. Retrieve the GUID of the computer with cscript **slmgr.vbs -did** 4. Run **cscript slmgr.vbs -dli <GUID>** 5. Verify that **License status** is set to **Licensed (activated)**.

Note

If Slmgr.vbs fails to activate the computer, the resulting error message advises you to run Slui.exe, along with the error code for more information. Slui.exe is not included in Server Core installations—it is available in <versions>.

1.2. Networking and firewall

Task	Steps
Configure your server to use a proxy server.	Run **netsh Winhttp set proxy <servername>:<port number>** **Note** Servers in Server Core mode cannot access the Internet through a proxy that requires a password to allow connections.
Configure your server to bypass the proxy for Internet addresses.	Run **netsh winttp set proxy <servername>:<port number>bypass-list="<local>"**
Display or modify IPSEC configuration.	Run **netsh ipsec**
Display or modify NAP configuration.	Run **netsh nap**
Display or modify IP-to-physical address translation.	Run **arp**
Display or configure the local routing table.	Run **route**
View or configure DNS server settings.	Run **nslookup**
Display protocol statistics and current TCP/IP network connections	Run **netstat**
Display protocol statistics and current TCP/IP connections using NetBIOS over TCP/IP (NBT).	Run **nbtstat**
Display hops for network connections.	Run **pathping**
Trace hops for network connections.	Run **tracert**
Display the configuration of the multicast router	Run **mrinfo**
Enable remote administration of the firewall.	Run **netsh advfirewall firewall set rule group=”Windows Firewall Remote Management” new enable=yes**

Note

See additional Windows PowerShell cmdlets for networking at http://technet.microsoft.com/library/hh826123, http://technet.microsoft.com/library/jj134956, and http://technet.microsoft.com/library/hh848620.

1.3. Updates and error reporting

Task	Steps
Install an update	Run **wusa <update>.msu /quiet**
List installed updates	Run **systeminfo**
Remove an update	1. Run **expand /f:* <update>.msu c:\test** 2. Navigate to c:\test\ and open <update>.xml in a text editor. 3. In <update>.xml, replace **Install** with **Remove** and save the file. 4. Run **pkgmgr /n:<update>.xml**
Configure automatic updates	• To verify the current setting, run **cscript scregedit.wsf /AU /v** • To enable automatic updates, run **cscript scregedit.wsf /AU 4** • To disable automatic updates, run **cscript scregedit.wsf /AU 1**
Enable error reporting	• To verify the current setting, run **serverWerOptin /query** • To automatically send detailed reports, run **serverWerOptin /detailed** • To automatically send summary reports, run **serverWerOptin /summary** • To disable error reporting, run **serverWerOptin /disable**
Participate in the Customer Experience Improvement Program (CEIP)	• To verify the current setting, run **serverCEIPOptin /query** • To enable CEIP, run **serverCEIPOptin /enable** • To disable CEIP, run **serverCEIPOptin /disable**

1.4. Services, processes, and performance

Task	Steps
List running services	Run `Get-Service`
Start a service	Run `Start-Service`
Stop a service	Run `Stop-Service`
Retrieve a list of running applications and associated processes	See http://technet.microsoft.com/library/dd347650.aspx.
Stop a process forcibly	See http://technet.microsoft.com/library/dd347650.aspx.
Start Task Manager	Run **taskmgr**
Manage the performance counters and logging with commands such as **typeperf**, **logman**, **relog**, **tracerprt**.	See http://go.microsoft.com/fwlink/?LinkId=84872.

1.5. Event logs

Use `Get-EventLog` and related cmdlets; see http://technet.microsoft.com/library/ee176846.

1.6. Disk and file system

Task	Steps
Manage disk partitions	For a complete list of commands, run **diskpart /?**
Manage software RAID	For a complete list of commands, run **diskraid /?**
Manage volume mount points	For a complete list of commands, run **mountvol /?**
Defragment a volume	For a complete list of commands, run **defrag /?**
Convert a volume to the NTFS file system	Run **convert <volume letter> /FS:NTFS**
Compact a file	For a complete list of commands, run **compact /?**
Administer open files	For a complete list of commands, run **openfiles /?**

Task	Steps
Administer VSS folders	For a complete list of commands, run **vssadmin /?**
Administer the file system	For a complete list of commands, run **fsutil /?**
Verify a file signature	For a complete list of commands, run **sigverif /?**
Take ownership of a file or folder	For a complete list of commands, run **icacls /?**

1.7. Hardware

Task	Steps
Add a driver for a new hardware device	1. Copy the driver to a folder at %homedrive%\<driver folder>. 2. Run **pnputil -i -a %homedrive%\<driver folder>\<driver>.inf**
Remove a driver for a hardware device	1. Obtain a list of loaded drivers by running **sc query type= driver** 2. Run **sc delete <service_name>**

Features Removed or Deprecated in Windows Server 2012

The following is a list of features and functionalities in Windows Server® 2012 that have either been removed from the product in the current release or are planned for potential removal in subsequent releases. It is intended for IT professionals who are updating operating systems in a commercial environment. This list is subject to change in subsequent releases and may not include every deprecated feature or functionality.

Features removed from Windows Server 2012

The following features and functionalities have been removed from this release of Windows Server 2012. Applications, code, or usage that depend on these features will not function in this release unless you employ an alternate method.

Active Directory Federation Services

- Support for applications that use the “NT Token mode” configuration of the web agent is removed. Applications are expected to move to Windows Identity Foundation and use the “Claims to Windows Token Service” to convert a UPN from a SAML token to a Windows token for consumption in the application.
- Support for “Resource Group” is removed. (Resource groups are explained at http://technet.microsoft.com/library/cc753670(WS.10).aspx)
- Support for using Active Directory Lightweight Directory Services (AD LDS) as an authentication store is removed
- You are required to migrate to the AD FS version in Windows Server 2012. In-place upgrade from AD FS 1.0 or “out of box” AD FS 2.0 is not supported.

Server Core components

Oclist.exe has been removed. Instead, use Dism.exe. For documentation on using Dism.exe, see http://technet.microsoft.com/library/dd772580(WS.10).aspx.

Clustering

- The Cluster Automation Server (MSClus) COM application programming interface (API) has been made an optional component called FailoverCluster-AutomationServer which is not installed by default. Cluster programmatic functionality is now provided by the Failover Cluster API and the Failover Cluster WMI provider.
- The Cluster.exe command-line interface has been made an optional component called FailoverCluster-CmdInterface which is not installed by default. Cluster command-line functionality is provided by the Failover Cluster PowerShell cmdlets.
- Support for 32-bit cluster resource DLLs has been deprecated. Use 64-bit versions instead.

Graphics

- Support for hardwire drivers for XDDM has been removed. As a result, XDDM graphics drivers will not load in Windows Server 2012. Instead, you can do any of the following:
  - Use the WDDM “basic display-only driver” included in the operating system.
  - Use a WDDM “display-only driver” provided by a hardware vendor.
  - Use a full WDDM driver provided by a hardware vendor.
- Support for native VGA via the PC/AT BIOS is removed. The WDDM “basic display-only driver” included in the operating system will replace this functionality. In UEFI systems, you may see fewer high-resolution (VESA) modes, but there is no other impact.

Hyper-V

- VM Chimney (also called TCP Offload) has been removed. The TCP chimney will not be available to guest operating systems.
- Support for Static VMQ has been removed. Drivers using NDIS 6.3 will automatically access Dynamic VMQ capabilities that are new in Windows Server 2012.

Networking

- NetDMA has been removed.
- Support for Token Rings has been removed.

Server roles

The Role Collector (Ceiprole.exe) and the associated API (Ceiprole.dll) have been removed. To collect telemetry data on server roles, use Server Manager.

Server Message Block

SMB.sys has been removed. The operating system now uses the Winsock Kernel (WSK) to provide the same functionality.

SQL Server

Versions of Microsoft SQL Server prior to 7.0 are no longer supported. Computers running Windows Server 2012 that connect to computers running SQL Server 6.5 (or earlier) will receive an error message.

Storage

- The Storage Manager for SANs snap-in for MMC has been removed. Instead, manage storage with PowerShell cmdlets and Server Manager.
- The Storage Explorer snap-in for MMC has been removed.
- The SCSIport host-bus adapter driver has been removed. Instead, either use a Storport driver or a different host-bus adapter.

Visual Studio

Support for Visual Studio Analyzer 2003 over ODBC, OLEDB, and ADO has been removed.

Windows Help

The Windows Help program (specifically, WinHlp32.exe, the executable file that opens *.hlp help files) has been removed from Windows since Windows Server 2008. Previously, downloadable packages that provide this functionality were made available (see http://support.microsoft.com/kb/917607). Starting with this release, no download will be provided

to enable you to view *.hlp files on Windows Server 2012. For this milestone release, Windows Help is also currently unsupported in Windows® 8.

Features deprecated starting with Windows Server 2012

The following features and functionalities are deprecated starting with this release. Eventually, they will be completely removed from the product, but they are still available in this release, sometimes with certain functionality removed. You should begin planning now to employ alternate methods for any applications, code, or usage that depend on these features.

Active Directory

Dcpromo.exe has been deprecated. In Windows Server 2012, if you run dcpromo.exe (without any parameters) from a command prompt, you receive a message directing you to Server Manager, where you can install Active Directory Domain Services using the Add Roles wizard. If you run **dcpromo /unattend** from a command prompt, you can still perform unattended installations that use Dcpromo.exe. This allows organizations to continue to use automated Active Directory Domain Services (AD DS) installation routines based on dcpromo.exe until they can rewrite those routines using Windows PowerShell. For more information, see http://technet.microsoft.com/library/hh472160.aspx.

Database management systems

- ODBC support for 16- and 32-bit applications and drivers is deprecated. Use 64-bit versions instead.
- ODBC/OLEDB support for Microsoft Oracle is deprecated. Migrate to drivers and providers supplied by Oracle.
- Jet Red RDBMS and ODBC drivers are deprecated.

Networking

The Network Driver Interface Specification (NDIS) version 5.0, 5.1, and 5.2 APIs are deprecated. New drivers for NDIS 6.0 must be written.

Hyper-V

- The WMI root\virtualization namespace is deprecated. The new namespace is root\virtualization\v2.
- Windows Authorization Manager (AzMan) is deprecated. You may need to use new management tools for virtual machines or redesign the authorization model.

Printing

The line printer daemon protocol (LPR/LPD) is deprecated. When this feature is eventually removed, clients that print to a server using this protocol, such as UNIX clients, will not be able to connect or print. Instead, UNIX clients should use IPP. Windows clients can connect to UNIX shared printers using the Windows Standard Port Monitor (see http://support.microsoft.com/kb/246868for more information).

Remote Data Service

The Remote Data service is deprecated. Migrate to the Windows Web Services API.

SMTP

SMTP and the associated management tools are deprecated. Though the functionality is still available in Windows Server 2012, you should begin using System.Net.Smtp. With this API, you will not be able to insert a message into a file for pickup; instead configure Web applications to connect on port 25 to another server using SMTP.

Subsystem for UNIX-based Applications

The Subsystem for UNIX-based Applications (SUA) is deprecated. If you use the SUA POSIX subsystem with this release, use Hyper-V to virtualize the server. If you use the tools provided by SUA, switch to Cygwin's POSIX emulation, or use either mingw-w64 (available from Sourceforge.net) or MinGW (available from MinGW.org) for doing a native port.

Transport protocols

- The Transport Driver Interface (TDI) is deprecated. Use Windows Filtering Platform instead.
- Layered Service Providers (LSP) are deprecated. Use Windows Filtering Platform instead.
- Winsock Direct is deprecated. Use Network Direct instead.

SNMP

SNMP is deprecated. Instead, use the Common Information Model (CIM), which is supported by the WS-Management web services protocol and implemented as Windows Remote Management.

SQL Server

- ODBC/OLEDB support for SQL is deprecated for versions beyond SQL Server 7 and SQL 2000. Migrate to SQL Native Client (SNAC) to use features provided by SQL Server 2005, SQL Server 2008, and later versions.
- SQLXMLX is deprecated. Migrate code to use SQLXML.

Windows System Resource Manager

Windows System Resource Manager (WSRM) is deprecated. Similar functionality is provided by Hyper-V.

WMI providers

- The WMI provider for Simple Network Management Protocol (SNMP) is deprecated because the SNMP service is being deprecated.
- The WMI provider for the Win32_ServerFeature API is deprecated.
- The WMI provider for Active Directory is deprecated. Manage Active Directory with PowerShell cmdlets.
- The WMI command-line tool (Wmic) is deprecated. Use PowerShell cmdlets instead.
- The namespace for version 1.0 of WMI is deprecated. Prepare to adapt scripts for a revised namespace.

XML

- XML-Data Reduced (XDR) schema elements are deprecated. Migrate Web applications that use this schema to the W3C Standards-compliant XML schema.
- The XSL pattern feature of MSXML3 is deprecated. Migrate Web applications that use this feature to the W3C Standards-compliant XML Path Language (XPath) feature set.

Portions of this software are based in part on the work of Hewlett-Packard Company. Because Microsoft has included the Hewlett-Packard Company software in this product, Microsoft is required to include the following text that accompanied such software:

Copyright © 2002, 2003 Hewlett-Packard Company.

About Notice:

This software is based on software available from http://mpvtools.sourceforge.net.

This software processes a format called MPV. MPV is an open specification for managing collections and multimedia playlists of photo, video, and music content and associated metadata and is available at no cost from the Optical Storage Technology Association. More information about the MPV specification can be found at http://www.osta.org/mpv.

OPENVISION DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL OPENVISION BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Copyright (c) 2006 by BEA, BMC, CA, Cisco, Dell, EMC, HP, IBM, Intel, Microsoft, and Sun. All rights reserved.

Permission to copy, display, and distribute this Service Modeling Language (SML) Schema Document, in any medium without fee or royalty is hereby granted, provided that you include the following on ALL copies of the SML Schema

Document, or portions thereof, that you make:

1. A link or URL to the SML Schema Document at this location:

   http://schemas.serviceml.org/sml/2007/02/sml.xsd
2. The copyright notice as shown in the SML Schema Document.

BEA, BMC, CA, Cisco, Dell, EMC, HP, IBM, Intel, Microsoft, and Sun (collectively, the “Authors”) each agree to grant you a royalty-free license, under reasonable, non-discriminatory terms and conditions to their respective patents that they deem necessary to implement the Service Modeling Language Schema Document.

THE SML SCHEMA DOCUMENT IS PROVIDED "AS IS," AND THE AUTHORS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE SML SCHEMA DOCUMENT ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.THE AUTHORS WILL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF OR RELATING TO ANY USE OR DISTRIBUTION OF THE SML SCHEMA DOCUMENT.

The name and trademarks of the Authors may NOT be used in any manner, including advertising or publicity pertaining to the SML Schema Document or its contents without specific, written prior permission. Title to copyright in the SML Schema Document will at all times remain with the Authors.

(c) 2001-2006 BEA Systems, Inc., BMC Software, CA, Inc.,

International Business Machines Corporation, Layer 7 Technologies, Microsoft Corporation, Inc., Novell, Inc. and VeriSign, Inc. All rights reserved.

Permission to copy, display, perform, modify and distribute WS-AUTHORIZATION.XSD (the "Document"), and to authorize others to do the foregoing, in any medium without fee or royalty is hereby granted for the purpose of developing and evaluating the Document.

BEA Systems, BMC Software, CA Inc., IBM, Layer 7 Technologies, Microsoft, Novell and VeriSign (collectively, the "Authors") each agree to grant a license to third parties, under royalty-free and otherwise reasonable, non-discriminatory terms and conditions, to their respective essential patent claims that they deem necessary to implement the Document.

THE DOCUMENT IS PROVIDED "AS IS," AND THE AUTHORS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE DOCUMENT IS SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY, PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.

THE AUTHORS WILL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF ANY USE OF THE DOCUMENT OR THE PERFORMANCE OR IMPLEMENTATION OF THE CONTENTS THEREOF.

You may remove these disclaimers from your modified versions of the Document provided that you effectively disclaim all warranties and liabilities on behalf of all copyright holders in the copies of any such modified versions you distribute.

The name and trademarks of the Authors may NOT be used in any manner, including advertising or publicity pertaining to the Document or its contents without specific, written prior permission. Title to copyright in the Document will at all times remain with the Authors.

(c) 2001-2006 BEA Systems Inc., International Business Machines Corporation, Microsoft Corporation, Inc., SAP AG, Sonic Software, and VeriSign, Inc. All rights reserved.

Permission to copy and display the WS-Policy Specification (the "Specification", which includes WSDL and schema documents), in any medium without fee or royalty is hereby granted, provided that you include the following on ALL copies of the WS-Policy Specification, that you make:

1. A link or URL to the WS-Policy Specification at one of the Authors' websites
2. The copyright notice as shown in the WS-Policy Specification.

BEA Systems, IBM, Microsoft, SAP, Sonic Software, and VeriSign (collectively, the "Authors") each agree to grant you a license, under royalty-free and otherwise reasonable, non-discriminatory terms and conditions, to their respective essential patent claims that they deem necessary to implement the WS-Policy Specification.

THE WS-POLICY SPECIFICATION IS PROVIDED "AS IS," AND THE AUTHORS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE WS-POLICY SPECIFICATION ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.

THE AUTHORS WILL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF OR RELATING TO ANY USE OR DISTRIBUTION OF THE WS-POLICY SPECIFICATION.

The name and trademarks of the Authors may NOT be used in any manner, including advertising or publicity pertaining to the WS-Policy Specification or its contents without specific, written prior permission. Title to copyright in the WS-Policy Specification will at all times remain with the Authors.

No other rights are granted by implication, estoppel or otherwise.

Intellectual Property

The IETF takes no position regarding the validity or scope of any Intellectual Property Rights or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; nor does it represent that it has made any independent effort to identify any such rights. Information on the procedures with respect to rights in RFC documents can be found in BCP 78 and BCP 79.

Copies of IPR disclosures made to the IETF Secretariat and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF on-line IPR repository at http://www.ietf.org/ipr.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights that may cover technology that may be required to implement this standard. Please address the information to the IETF at ietf-ipr@ietf.org.

http://www.microsoft.com/opensource/licenses.mspx

This license governs use of the accompanying software. If you use the software, you accept this license. If you do not accept the license, do not use the software.

Definitions

The terms "reproduce," "reproduction," "derivative works," and "distribution" have the same meaning here as under U.S. copyright law. A "contribution" is the original software, or any additions or changes to the software.

A "contributor" is any person that distributes its contribution under this license.

"Licensed patents" are a contributor's patent claims that read directly on its contribution.

Grant of Rights

(A) Copyright Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free copyright license to reproduce its contribution, prepare derivative works of its contribution, and distribute its contribution or any derivative works that you create.

(B) Patent Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free license under its licensed patents to make, have made, use, sell, offer for sale, import, and/or otherwise dispose of its contribution in the software or derivative works of the contribution in the software.

Conditions and Limitations

(A) No Trademark License- This license does not grant you rights to use any contributors' name, logo, or trademarks.

(B) If you bring a patent claim against any contributor over patents that you claim are infringed by the software, your patent license from such contributor to the software ends automatically.

(C) If you distribute any portion of the software, you must retain all copyright, patent, trademark, and attribution notices that are present in the software.

(D) If you distribute any portion of the software in source code form, you may do so only under this license by including a complete copy of this license with your distribution. If you distribute any portion of the software in compiled or object code form, you may only do so under a license that complies with this license.

(E) The software is licensed "as-is." You bear the risk of using it. The contributors give no express warranties, guarantees, or conditions. You may have additional consumer rights under your local laws which this license cannot change. To the extent permitted under your local laws, the contributors exclude the implied warranties of merchantability, fitness for a particular purpose and non-infringement.

==========

This product includes cryptographic software written by Eric Young (eay@cryptsoft.com). This product includes software written by Tim Hudson (tjh@cryptsoft.com).

Original SSLeay License

Copyright (C) 1995-1998 Eric Young (eay@cryptsoft.com)

All rights reserved.

This package is an SSL implementation written by Eric Young (eay@cryptsoft.com).

The implementation was written so as to conform with Netscapes SSL.

This library is free for commercial and non-commercial use as long as the following conditions are adhered to. The following conditions apply to all code found in this distribution, be it the RC4, RSA, lhash, DES, etc., code; not just the SSL code. The SSL documentation included with this distribution is covered by the same copyright terms except that the holder is Tim Hudson (tjh@cryptsoft.com).

Copyright remains Eric Young's, and as such any Copyright notices in the code are not to be removed.

If this package is used in a product, Eric Young should be given attribution as the author of the parts of the library used. This can be in the form of a textual message at program startup or in documentation (online or textual) provided with the package.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:Redistributions of source code must retain the copyright notice, this list of conditions and the following disclaimer.Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

All advertising materials mentioning features or use of this software must display the following acknowledgement:

"This product includes cryptographic software written by Eric Young (eay@cryptsoft.com)"

The word 'cryptographic' can be left out if the routines from the library being used are not cryptographic related :-).

If you include any Windows specific code (or a derivative thereof) from the apps directory (application code) you must include an acknowledgement:

"This product includes software written by Tim Hudson (tjh@cryptsoft.com)"

THIS SOFTWARE IS PROVIDED BY ERIC YOUNG ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT

LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

The license and distribution terms for any publically available version or derivative of this code cannot be changed. i.e. this code cannot simply be copied and put under another distribution license [including the GNU Public License.]

Portions of this software are based in part on FreeBSD. Because Microsoft has included the FreeBSD software in this product, Microsoft is required to include the following text that accompanied such software:

The Institute of Electrical and Electronics Engineers and the American National Standards Committee X3, on Information Processing Systems have given us permission to reprint portions of their documentation.

In the following statement, the phrase ``this text'' refers to portions of the system documentation. Portions of this text are reprinted and reproduced in electronic form in the second BSD Networking Software Release, from IEEE Std 1003.1-1988, IEEE Standard Portable Operating System Interface for Computer Environments (POSIX), copyright C 1988 by the Institute of Electrical and Electronics Engineers, Inc. In the event of any discrepancy between these versions and the original IEEE Standard, the original IEEE Standard is the referee document.

In the following statement, the phrase ``This material'' refers to portions of the system documentation.

This material is reproduced with permission from American National Standards Committee X3, on Information Processing Systems. Computer and Business Equipment Manufacturers Association (CBEMA), 311 First St., NW, Suite 500, Washington, DC 20001-2178. The developmental work of Programming Language C was completed by the X3J11 Technical Committee.

The views and conclusions contained in the software and documentation are those of the authors and should not be interpreted as representing official policies, either expressed or implied, of the Regents of the University of California.

NOTE: The copyright of UC Berkeley's Berkeley Software Distribution ("BSD") source has been updated. The copyright addendum may be found at ftp://ftp.cs.berkeley.edu/pub/4bsd/README.Impt.License.Change and is includedbelow.

July 22, 1999

To All Licensees, Distributors of Any Version of BSD:

As you know, certain of the Berkeley Software Distribution ("BSD") source code files require that further distributions of products containing all or portions of the software, acknowledge within their advertising materials that such products contain software developed by UC Berkeley and its contributors.

Specifically, the provision reads: “All advertising materials mentioning features or use of this software must display the following acknowledgement:

This product includes software developed by the University of California, Berkeley and its contributors."

Effective immediately, licensees and distributors are no longer required to include the acknowledgement within advertising materials. Accordingly, the foregoing paragraph of those BSD Unix files containing it is hereby deleted in its entirety.

Migrate Roles and Features to Windows Server

Migration documentation and tools ease the process of migrating server roles, features, operating system settings, and data from an existing server that is running Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, or Windows Server 2012 R2 to a computer that is running Windows Server 2012 R2. By using migration guides linked to on this page (and where appropriate, Windows Server Migration Tools) to migrate roles, role services, and features, you can simplify deployment of new servers (including those that are running the Server Core installation option of Windows Server 2012 R2 or Windows Server 2012, and virtual servers), reduce migration downtime, increase accuracy of the migration process, and help eliminate conflicts that could otherwise occur during the migration process.

Most of the migration documentation and tools featured in this section support cross-architecture migrations (x86-based to x64-based computing platforms), migrations between physical and virtual environments, and migrations between both the full and Server Core installation options of the Windows Server operating system, where available.

In Windows Server 2012 and later releases of Windows Server, Windows Server Migration Tools supports cross-subnet migrations.

Migration guides

The following are available resources for migrating roles to Windows Server 2012 or Windows Server 2012 R2.

Windows Server roles, role services, and features

Windows Server Migration guides provide you with instructions for migrating a single role, role service, or feature to a server that is running Windows Server 2012 or Windows Server 2012 R2. Guides do not contain instructions for migration when the source server is running multiple roles. If your server is running multiple roles, it is recommended that you design a custom migration procedure specific to your server environment, based on the information provided in other migration guides.

- Migrate Roles and Features to Windows Server 2012 R2
- Migrate Roles and Features to Windows Server 2012

Windows Server Migration Tools

Windows Server Migration Tools, available as a feature in Windows Server 2012 R2 and Windows Server 2012, allows an administrator to migrate some server roles, features, operating system settings, shares, and other data from computers that are running certain editions of Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, or Windows Server 2012 R2 to computers that are running Windows Server 2012 or Windows Server 2012 R2.

Not all migrations require or use Windows Server Migration Tools. Guides for migrations that require Windows Server Migration Tools clearly state that Windows Server Migration Tools setup is part of the migration process, and provide specific instructions for how to use Windows Server Migration Tools.

To use Windows Server Migration Tools, the feature must be installed on both source and destination computers as described in the following guide.

Install, use, and remove Windows Server Migration Tools

Active Directory Certificate Services Migration Guide for Windows Server 2012 R2

About this guide

This document provides guidance for migrating a certification authority (CA) to a server that is running Windows Server 2012 R2 from a server that is running Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, Windows Server 2003 R2, or Windows Server 2003.

Target audience

- Administrators or IT operations engineers responsible for planning and performing CA migration.

- Administrators or IT operations engineers responsible for the day-to-day management and troubleshooting of networks, servers, client computers, operating systems, or applications.
- IT operations managers accountable for network and server management.
- IT architects responsible for computer management and security throughout an organization.

Supported migration scenarios

This guide provides you with instructions for migrating an existing server that is running Active Directory® Certificate Services (AD CS) to a server that is running Windows Server 2008 R2 or Windows Server 2012 R2. This guide does not contain instructions for migration when the source server is running multiple roles. If your server is running multiple roles, you should design a custom migration procedure that is specific to your server environment, based on the information provided in other role migration guides. To view migration guides for other server roles, see Migrating Roles and Features in Windows Server (http://go.microsoft.com/fwlink/?LinkID=128554).

Note

This guide can be used to migrate a CA from a source server that is also a domain controller to a destination server with a different name. However, migration of a domain controller is not covered by this guide. For information about Active Directory Domain Services (AD DS) migration, see Active Directory Domain Services and DNS Server Migration Guide (http://go.microsoft.com/fwlink/?LinkId=179357).

Supported operating systems

This guide supports migrations from source servers running the operating system versions and service packs listed in the following table. All migrations described in this document assume that the destination server is running Windows Server 2012 R2 as specified in the following table.

Source server processor	Source server operating system	Destination server operating system	Destination server processor
x64-based	Windows Server 2012 R2	Windows Server 2012 R2, Server with a GUI only (not Server Core or Minimal Server Interface)	x64-based
x64-based	Windows Server 2012	Windows Server 2012 R2 or Windows Server 2012, Server with a GUI only (not Server Core or Minimal Server Interface)	x64-based

Source server processor	Source server operating system	Destination server operating system	Destination server processor
x64-based	Windows Server 2008 R2	Windows Server 2012 R2or Windows Server 2012, Server with a GUI only (not Server Core or Minimal Server Interface) or Windows Server 2008 R2, both full and Server Core installation options	x64-based
x86-based or x64-based	Windows Server 2008	Windows Server 2012 R2or Windows Server 2012, Server with a GUI only (not Server Core or Minimal Server Interface) or Windows Server 2008 R2, both full and Server Core installation options	x64-based
x86-based or x64-based	Windows Server 2003 R2	Windows Server 2012 R2or Windows Server 2012, Server with a GUI only (not Server Core or Minimal Server Interface) or Windows Server 2008 R2, both full and Server Core installation options	x64-based
x86-based or x64-based	Windows Server 2003 with Service Pack 2	Windows Server 2012 R2or Windows Server 2012, Server with a GUI only (not Server Core or Minimal Server Interface) or Windows Server 2008 R2, both full and Server Core installation options	x64-based

Note

In-place upgrades directly from Windows Server 2003 with Service Pack 2 or Windows Server 2003 R2 to Windows Server 2012 R2 are not supported. If you are running an x64-based computer, you can upgrade the CA role service from Windows Server 2003 with Service Pack 2 or Windows Server 2003 R2 to Windows Server 2008 or Windows Server 2008 R2 first and then upgrade to Windows Server 2012 R2 or Windows Server 2012.

What this guide does not provide

- Procedures to upgrade to Windows Server 2012 R2, Windows Server 2012, or Windows Server 2008 R2
- Procedures to migrate additional server roles
- Procedures to migrate additional AD CS role services

In general, migration is not required for the following AD CS role services. Instead, you can install and configure these role services on computers running Windows Server 2008 R2 or Windows Server 2012 by completing the role service installation procedures. For information about the impact of CA migration on other AD CS role services, see Impact of migration on other computers in the enterprise.

- CA Web Enrollment (http://go.microsoft.com/fwlink/?LinkId=179360)
- Online Responder (http://go.microsoft.com/fwlink/?LinkId=143098)
- Network Device Enrollment (http://go.microsoft.com/fwlink/?LinkId=179362)
- Certificate Enrollment Web Services (http://go.microsoft.com/fwlink/?LinkId=179363)

CA migration overview

Certification authority (CA) migration involves several procedures, which are covered in the following sections.

Warning

During the migration procedure, you are asked to turn off your existing CA (either the computer or at least the CA service). You are asked to name the destination CA with the same name that you used for the original CA. The computer name, (hostname or NetBIOS name), does not have to match that of the original CA. However, the destination CA name must match that of the source CA. Further, the destination CA name must not be identical to the destination computer name.

Note

It is possible to install a new PKI hierarchy while still leveraging an existing PKI hierarchy. However, doing so requires designing a new PKI, which is not covered in this guide. For an informal overview of how a dual PKI could work for an organization, see the following Ask DS blog post: Moving Your Organization from a Single Microsoft CA to a Microsoft Recommended PKI.

Preparing to migrate

- Preparing your destination server
- Backing up your source server
- Preparing your source server

Migrating the certification authority

- Backing up a CA database and private key
- Backing up CA registry settings
- Backing up CAPolicy.inf
- Removing the CA role service from the source server
- Removing the source server from the domain
- Joining the destination server to the domain
- Adding the CA role service to the destination server
- Restoring the CA database and configuration on the destination server
- Granting permissions on AIA and CDP containers
- Additional procedures for failover clustering (optional)

Verifying the migration

- Verifying certificate enrollment
- Verifying CRL publishing

Post-migration tasks

- Upgrading certificate templates in Active Directory Domain Services (AD DS)
- Retrieving certificates after a host name change
- Restoring Active Directory Certificate Services (AD CS) to the source server in the event of migration failure
- Troubleshooting migration

Impact of migration

Impact of migration on the source server

The CA migration procedures described in this guide include decommissioning the source server after migration is completed and CA functionality on the destination server has been verified. If the source server is not decommissioned, then the source server and destination server must have different names. Additional steps are required to update the CA configuration on the destination server if the name of the destination server is different from the name of the source server.

Impact of migration on other computers in the enterprise

During migration, the CA cannot issue certificates or publish CRLs.

To ensure that revocation status checking can be performed by domain members during CA migration, it is important to publish a CRL that is valid beyond the planned duration of the migration.

Because the authority identification access and CRL distribution point extensions of previously issued certificates may reference the name of the source CA, it is important to either continue to publish CA certificates and CRLs to the same location or provide a redirection solution. For an example of configuring IIS redirection, see Redirecting Web Sites in IIS 6.0.

Permissions required to complete the migration

To install an enterprise CA or a standalone CA on a domain member computer, you must be a member of the Enterprise Admins group or Domain Admins group in the domain. To install a standalone CA on a server that is not a domain member, you must be a member of the local Administrators group. Removal of the CA role service from the source server has the same group membership requirements as installation.

Estimated duration

The simplest CA migration can typically be completed within one to two hours. The actual duration of CA migration depends on the number of CAs and the sizes of CA databases.

- Migrating Roles and Features in Windows Server

Prepare to Migrate

To reduce the duration of the migration process, you can complete the procedures detailed in this topic before beginning the migration process and taking the certification authority (CA) offline.

- Preparing your destination server
- Backing up your source server
- Preparing your source server

Preparing your destination server

Hardware requirements for the destination server

The hardware requirements to install any of the Active Directory Certificate Services (AD CS) role services are the same as the minimum and recommended configurations for installation of Windows Server 2012 R2. This section includes the general hardware recommendations for Windows Server 2012 R2. For detailed requirements, see System Requirements and Installation Information for Windows Server 2012 R2.

Hardware requirements for AD CS

In addition to the hardware requirements for the operating system, consider these storage and performance requirements for optimal CA performance and availability:

- The disk space requirements for a CA database depend on the number of certificates that the CA issues. Because a CA stores certificate requests, the issued certificates, and optionally, archived key material, 64 KB of database space per certificate is recommended.
- The operating system, the CA database, and the CA log files should be stored on separate physical disk drives in a multidisk configuration. For optimal CA performance and reliability, consider a redundant array of independent disks (RAID) system, such as RAID 5 for the CA database and log files and RAID 1 or RAID 0+1 for the operating system. A recommended minimum hard disk speed is 10,000 RPM.
- Processor power is generally more important to CA performance than system memory capacity.
- Failover clusters have additional hardware, software, and networking requirements. For more information, see Failover Cluster Requirements (http://go.microsoft.com/fwlink/?LinkId=179369).
- If a hardware security module (HSM) is used by the CA, consult with your HSM vendor to verify compatibility with Windows Server 2012 R2.

Software requirements for the destination server

Enterprise CAs can be installed on computers running any version of Windows Server 2012 R2.

When AD CS in Windows Server 2012 R2 is installed in an Active Directory Domain Services (AD DS) domain, the AD DS schema version must be at least 30 and all domain controllers in the domain must be running one of the following operating systems:

- Windows Server 2012 R2
- Windows Server 2012
- Windows Server 2008 with Service Pack 1 (SP1)
- Windows Server 2008
- Windows Server 2003 R2
- Windows Server 2003 with Service Pack 2 (SP2)
- Windows Server 2003 with SP1

- Windows Server 2003

Note
Domain controllers running Windows 2000 Server with Service Pack 4 (SP4) or Windows 2000 Server with Service Pack 3 (SP3) are technically compatible with AD CS deployments. However, the use of Windows 2000 Server is not recommended because Mainstream Support is no longer available for this operating system. For more information, see Microsoft Support Lifecycle (http://go.microsoft.com/fwlink/?LinkId=117347).

If an HSM is used by the CA, consult your HSM vendor to verify cryptographic service provider (CSP) and key service provider (KSP) compatibility with Windows Server 2012 R2 depending on the operating system to be used.

Installing the Operating System

To reduce the duration of the migration process, you can prepare the destination server by completing the following procedures before beginning the migration process and taking the source CA offline.

- Review the hardware and software requirements in the previous sections.
- Install Windows Server 2012 R2. For more information, see System Requirements and Installation Information for Windows Server 2012 R2.
- Install updates by using Windows Update.
- (Optional) Install failover clustering by reviewing the Active Directory Certificate Services (AD CS) Clustering documentation.

If you are migrating to a Server Core installation you should configure the server for remote management, which is disabled by default.

Configure remote management on Server Core

1. Log on as an administrator.
2. Type **sconfig.cmd** and press ENTER.
3. Perform the following tasks by completing the procedures described in Configuring a Server Core installation with Sconfig.cmd:
   a. Configure network settings as required for your environment.
   b. Join the server to your domain. This step is required if you are setting up an enterprise CA and optional if you are setting up a standalone CA.
   c. Configure Remote Management to enable **MMC Remote Management** or **Server Manager Remote Management**.
   d. Enable **Remote Desktop** (optional).
4. Type **13** and press ENTER to close sconfig.cmd.

Note

For information on configuring remote management in see Configure Remote Management in Server Manager.

Backing up your source server

Back up your source server to prepare for recovery of the source CA in the event of migration failure.

For information about backing up Windows Server 2012 R2 or Windows Server 2012, see Windows Server Backup.

For more information about creating backups in Windows Server 2008, see the Windows Server Backup Step-by-Step Guide for Windows Server 2008 (http://go.microsoft.com/fwlink/?LinkId=119141).

For more information about creating system state backups in Windows Server 2003, see article 326216 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=117369).

Detailed procedures for backing up the source CA database, private key, and registry settings are provided in the topic Migrating the Certification Authority.

Preparing your source server

To reduce the duration and impact of CA migration, the following procedures should be completed before you begin migration:

- Back up the CA templates list (required only for enterprise CAs).
- Record the CA's CSP and signature algorithm.
- Publish a CRL with an extended validity period.

Backing up a CA templates list

An enterprise CA can have certificate templates assigned to it. You should record the assigned certificate templates before beginning the CA migration. The information is not backed up with the CA database or registry settings backup. This is because certificate templates and their association with enterprise CAs are stored in AD DS. You will need to add the same list of templates to the destination server to complete CA migration.

Note

It is important that the certificate templates assigned to the source CA are not changed after this procedure is completed.

You can determine the certificate templates assigned to a CA by using the Certification Authority snap-in or the **Certutil.exe –catemplates** command.

To record a CA templates list by using the Certification Authority snap-in

1. Log on with local administrative credentials to the CA computer.
2. Open the Certification Authority snap-in.

3. In the console tree, expand **Certification Authority**, and click **Certificate Templates**.
4. Record the list of certificate templates by taking a screen shot or by typing the list into a text file.

To record a CA templates list by using Certutil.exe

1. Log on with local administrative credentials to the CA computer.
2. Open a Command Prompt window.
3. Type the following command and press ENTER.

```
certutil.exe -catemplates > catemplates.txt
```

4. Verify that the catemplates.txt file contains the templates list.

Note
If no certificate templates are assigned to the CA, the file contains an error message: 0x80070490 (Element not found).

Recording a CA's signature algorithm and CSP

During CA installation on the destination server, you can specify the signature algorithm and CSP used by the CA, or accept the default configuration. If your source CA is not using the default configuration, then you should complete the following procedure to record the CSP and signature algorithm.

Note
If an HSM is used by the source CA, follow procedures provided by the HSM vendor to determine the HSM CSP.

To record a CA's CSP by using Certutil.exe

1. Log on with local administrative credentials to the CA computer.
2. Open a Command Prompt window.
3. Type the following command and press ENTER.

```
certutil.exe -getreg ca\csp\* > csp.txt
```

4. Verify that the csp.txt file contains the CSP details.

Publishing a CRL with an extended validity period

Before beginning CA migration, it is a good practice to publish a CRL with a validity period that extends beyond the planned migration period. The validity period of the CRL should be at least the length of time that is planned for the migration. This is necessary to enable certificate validation processes on client computers to continue during the migration period.

You should publish a CRL with an extended validity period for each CA being migrated. This procedure is particularly important in the case of a root CA because of the potentially large number of certificates that would be affected by the unavailability of a CRL.

By default, the CRL validity period is equal to the CRL publishing period plus 10 percent. After determining an appropriate CRL validity period, set the CRL publishing interval and manually publish the CRL by completing the following procedures:

Important
Record the value of the CRL publishing period before changing it. After migration is complete, the CRL publishing period should be reset to its previous value.

- Schedule the publication of the certificate revocation list
- Manually publish the certificate revocation list

Caution
Client computers download a new CRL only after the validity period of a locally cached CRL expires. Therefore, you should not use a CRL validity period that is excessively long.

Next steps

After completing the procedures to prepare the source and destination servers, you should review the topic Migrating the Certification Authority and complete the procedures appropriate for your specific migration scenario.

See also

- Active Directory Certificate Services Migration Guide for Windows Server 2012 R2
- Migrating the Certification Authority
- Verifying the Certification Authority Migration
- Post-Migration Tasks
- Migrating Roles and Features in Windows Server

Migrating the Certification Authority

Review all procedures in this topic and complete only the procedures that are required for your migration scenario.

- Backing up a CA database and private key
- Backing up CA registry settings
- Backing up CAPolicy.inf
- Removing the CA role service from the source server
- Removing the source server from the domain
- Joining the destination server to the domain
- Adding the CA role service to the destination server
- Restoring the CA database and configuration on the destination server

- Granting permissions on AIA and CDP containers
- Additional procedures for failover clustering

  This is an optional set of steps if you are migrating to a failover cluster.

Backing up a CA database and private key

You can back up the CA database and private key by using the Certification Authority snap-in or by using Certutil.exe at a command prompt. Complete either one of the backup procedures described in this section.

Note

If a hardware security module (HSM) is used by the CA, back up the private keys by following procedures provided by the HSM vendor.

After completing backup steps, the Active Directory Certificate Services service (Certsvc) should be stopped to prevent issuance of additional certificates. Before adding the CA role service to the destination server, the CA role service should be removed from the source server.

The backup files created during these procedures should be stored in the same location to simplify the migration. The location should be accessible from the destination server; for example, removable media or a shared folder on the destination server or another domain member.

Backing up a CA database and private key by using the Certification Authority snap-in

The following procedure describes the steps to back up the CA database and private key by using the Certification Authority snap-in while logged on to the source CA.

Note

If you prefer, you can use the certutil application to back up the CA database and private key. Using certutil for CA backup is covered in the next section.

You must use an account that is a CA administrator. On an enterprise CA, the default configuration for CA administrators includes the local Administrators group, the Enterprise Admins group, and the Domain Admins group. On a standalone CA, the default configuration for CA administrators includes the local Administrators group.

To back up a CA database and private key by using the Certification Authority snap-in

1. Choose a backup location and attach media, if necessary.
2. Log on to the source CA.
3. Open the **Certification Authority** snap-in.
4. Right-click the node with the CA name, point to **All Tasks**, and then click **Back Up CA**.
5. On the **Welcome** page of the CA Backup wizard, click **Next**.
6. On the **Items to Back Up** page, select the **Private key and CA certificate** and **Certificate database and certificate database log** check boxes, specify the backup

location, and then click **Next**.

7. On the **Select a Password** page, type a password to protect the CA private key, and click **Next**.

   Security

   Use a strong password; for example, at least eight characters long with a combination of uppercase and lowercase characters, numbers, and punctuation characters.

8. On the **Completing the Backup Wizard** page, click **Finish**.
9. After the backup completes, verify the following files in the location you specified:
   - *CAName*.p12 containing the CA certificate and private key
   - Database folder containing files certbkxp.dat, edb#####.log, and *CAName*.edb
10. Open a Command Prompt window, and type **net stop certsvc** to stop the Active Directory Certificate Services service.

    Important

    The service should be stopped to prevent issuance of additional certificates. If certificates are issued by the source CA after a database backup is completed, repeat the CA database backup procedure to ensure the database backup contains all issued certificates.

11. Copy all backup files to a location that is accessible from the destination server; for example, a network share or removable media.

    Security

    The private key must be protected against compromise. Protect a shared folder by limiting its access control list to authorized CA administrators. Protect removable media against unauthorized access and damage.

Backing up a CA database and private key by using Windows PowerShell

The following procedure describes the steps to back up the CA database and private key by using the Backup-CARoleService cmdlet while logged on to the source CA.

Important

You must use an account that is a CA administrator. On an enterprise CA, the default configuration for CA administrators includes the local Administrators group, the Enterprise Admins group, and the Domain Admins group. On a standalone CA, the default configuration for CA administrators includes the local Administrators group.

To back up a CA database and private key by using Windows PowerShell

1. Log on with local administrative credentials to the CA computer.
2. Right-click **Windows PowerShell** and click **Run as Administrator**.

3. Type the following command and press ENTER:

```
Backup-CARoleService –path <BackupDirectory>
```

Note

BackupDirectory specifies the directory in which the backup files are created. The specified value can be a relative or absolute path. If the specified directory does not exist, it is created. The backup files are created in a subdirectory named Database.

4. The service must be stopped to prevent issuance of additional certificates. Type the following command and press ENTER:

```
Stop-service certsvc
```

5. After the backup completes, verify the following files in the location you specified:
   - *CAName*.p12 containing the CA certificate and private key
   - Database folder containing files certbkxp.dat, edb#####.log, and *CAName*.edb
6. Copy all backup files to a location that is accessible from the destination server; for example, a network share or removable media.

Security

The private key must be protected against compromise. Protect a shared folder by granting permission to only authorized CA administrators. Protect removable media against unauthorized access and damage.

Backing up a CA database and private key by using Certutil.exe

The following procedure describes the steps to back up the CA database and private key by using Certutil.exe while logged on to the source CA.

Important

You must use an account that is a CA administrator. On an enterprise CA, the default configuration for CA administrators includes the local Administrators group, the Enterprise Admins group, and the Domain Admins group. On a standalone CA, the default configuration for CA administrators includes the local Administrators group.

To back up a CA database and private key by using Certutil.exe

1. Log on with local administrative credentials to the CA computer.
2. Open a Command Prompt window.
3. Type **Certutil.exe –backupdb** <*BackupDirectory*> and press ENTER.
4. Type **Certutil.exe –backupkey** <*BackupDirectory*> and press ENTER.

Note

BackupDirectory specifies the directory in which the backup files are created. The specified value can be a relative or absolute path. If the specified directory does not exist, it is created. The backup files are created in a subdirectory named

Database.

5. Type a password at the prompt, and press ENTER. You must retain a copy of the password to access the key during CA installation on the destination server.

   Security

   Use a strong password; for example, at least eight characters with a combination of uppercase and lowercase characters, numbers, and symbols.

6. Type **net stop certsvc** and press ENTER to stop the Active Directory Certificate Services service. The service must be stopped to prevent issuance of additional certificates.
7. After the backup completes, verify the following files in the location you specified:
   - *CAName*.p12 containing the CA certificate and private key
   - Database folder containing files certbkxp.dat, edb#####.log, and *CAName*.edb
8. Copy all backup files to a location that is accessible from the destination server; for example, a network share or removable media.

   Security

   The private key must be protected against compromise. Protect a shared folder by granting permission to only authorized CA administrators. Protect removable media against unauthorized access and damage.

Backing up CA registry settings

Complete one of the following procedures to back up the CA registry settings.

The files created during the backup procedure should be stored in the same location as the database and private key backup files to simplify the migration. The location should be accessible from the destination server; for example, removable media or a shared folder on the destination server or another domain member.

You must be logged on to the source CA using an account that is a member of the local Administrators group.

To back up CA registry settings by using Regedit.exe

1. Click **Start**, point to **Run**, and type **regedit** to open the Registry Editor.
2. In `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CertSvc`, right-click **Configuration**, and then click **Export**.
3. Specify a location and file name, and then click **Save**. This creates a registry file containing CA configuration data from the source CA.
4. Copy the registry file to a location that is accessible from the destination server; for example, a shared folder or removable media.

To back up CA registry settings by using Reg.exe

1. Open a Command Prompt window.
2. Type **reg export HKLM\SYSTEM\CurrentControlSet\Services\CertSvc\Configuration** <*output file*>.reg and press ENTER.
3. Copy the registry file to a location that is accessible from the destination server; for example, a shared folder or removable media.

Backing up CAPolicy.inf

If your source CA is using a custom CAPolicy.inf file, you should copy the file to the same location as the source CA backup files.

The CAPolicy.inf file is located in the %SystemRoot% directory, which is usually C:\Windows.

Removing the CA role service from the source server

It is important to remove the CA role service from the source server after completing backup procedures and before installing the CA role service on the destination server. Enterprise CAs and standalone CAs that are domain members store in Active Directory Domain Services (AD DS) configuration data that is associated with the common name of the CA. Removing the CA role service also removes the CA's configuration data from AD DS. Because the source CA and destination CA share the same common name, removing the CA role service from the source server after installing the CA role service on the destination server removes configuration data that is required by destination CA and interferes with its operation.

The CA database, private key, and certificate are not removed from the source server by removing the CA role service. Therefore, reinstalling the CA role service on the source server restores the source CA if migration fails and performing a rollback is required. See Restoring Active Directory Certificate Services (AD CS) to the source server in the event of migration failure.

Warning

Although it is not recommended, some administrators may choose to leave the CA role service installed on the source server to enable the source CA to be brought online quickly in the case of migration failure. If you choose not to remove the CA role service from the source server before installing the CA role service on the destination server, it is important that you disable the Active Directory Certificate Services service (Certsvc) and shut down the source server before installing the CA role service on the destination server. Do not remove the CA role service from the source server after completing the migration to the destination server. Removing the CA role service from the source server after migrating to the destination server interferes with the operation of the destination CA.

- To remove the CA on a computer running Windows Server 2003, use the Add/Remove Windows Components wizard.
- To remove the CA on a computer running Windows Server 2008 or later, use the Remove Roles and Features Wizard in Server Manager.

Removing the source server from the domain

Because computer names must be unique within an Active Directory domain, it is necessary to remove the source server from its domain and delete the associated computer account from Active Directory before joining the destination server to the domain.

If you have access to a domain member computer running Windows Server 2008 or later , complete the following procedure to remove the source server from the domain by using Netdom.exe.

If you do not have access to a computer running Windows Server 2008 or later, then complete the procedure Join a Workgroup (http://go.microsoft.com/fwlink/?LinkId=207683). Joining a workgroup also removes a domain member computer from its domain.

To remove the source server from the domain by using Netdom.exe

1. On a domain member computer running Windows Server 2008 or later, open an elevated Command Prompt window.
2. Type **netdom remove** <*source server name*> /d:<*domain name*> /ud:<*domain user account*> /pd:* and press ENTER. For additional command-line options, see Netdom remove syntax (http://go.microsoft.com/fwlink/?LinkID=207681).

   Tip
   Using Windows PowerShell, you can run the command: **remove-computer** <*computer name*>

   For more information, see Remove-Computer (http://technet.microsoft.com/en-us/library/dd347703.aspx).
3. Shut down the source server.

After removing the source server from its domain, delete the source server's computer account from AD DS by completing the procedure Delete a Computer Account (http://go.microsoft.com/fwlink/?LinkID=138386).

Tip
You can also use Windows PowerShell to remove the computer account from AD DS. For more information, see Remove-ADComputer (http://technet.microsoft.com/library/hh852313).

Joining the destination server to the domain

Before joining the destination server to the domain, change the computer name to the same name as the source server. Then complete the procedure to join the destination server to the domain.

If your destination server is running on the Server Core installation option, you must use the command-line procedure.

To rename the destination server, you must be a member of the local Administrators group. To join the server to the domain, you must be a member of the Domain Admins or Enterprise Admins groups, or have delegated permissions to join the destination server to an organizational unit (OU) in the domain.

Important
If you are migrating a standalone CA that is not a domain member, complete only the steps to rename the destination server and do not join the destination server to the domain.

To join the destination server to the domain by using Netdom.exe

1. On the destination server, open an elevated Command Prompt window.
2. Type **netdom renamecomputer** <*computer name*> /newname:<*new computer name*>

   Tip
   Using Windows PowerShell, you can run the command: **rename-computer** <*new computer name*>
3. Restart the destination server.
4. After the destination server restarts, log on by using an account that has permission to join computers to the domain.
5. Open an elevated Command Prompt window, type **netdom join** <*computer name*> /d:<*domain name*> /ud:<*domain user account*> /pd:* [/ou:<*OU name*>] and press ENTER. For additional command-line options, see Netdom join syntax (http://go.microsoft.com/fwlink/?LinkID=207680).

   Tip
   Using Windows PowerShell, you can run the command: **add-computer -DomainName** <*domain name*>

   For more information, see Add-Computer (http://technet.microsoft.com/en-us/library/dd347556.aspx).
6. Restart the destination server.

Adding the CA role service to the destination server

This section describes two different procedures for adding the CA role service to the destination server, including special instructions for using failover clustering.

Review the following statements to determine which procedures to complete.

- If your destination server is running the Server Core installation option, you can use Windows PowerShell to install the CA. See Install-AdcsCertificationAuthority for more information.
- If you are migrating to a CA that uses failover clustering, you must review the section "Special instructions for migrating to a failover cluster" and complete the procedures Importing the CA certificate and Adding the CA role service by using Server Manager.
- If you are migrating to a CA that uses an HSM, you must complete the procedures Importing the CA certificate and Adding the CA role service by using Server Manager.
- If none of the above statements describes your migration scenario, you can use the following procedure to add the CA role service: Adding the CA role service by using Server Manager. If you use Server Manager, you must also complete the procedure Importing the CA certificate.

Special instructions for migrating to a failover cluster

If you are migrating to a failover cluster, the procedures to import the CA certificate and add the CA role service must be completed on each cluster node. After the CA role service is added to each node, you should stop the Active Directory Certificate Services service (Certsvc).

Additionally, it is important to ensure that the shared storage used by the CA is online and assigned to the node you are adding the CA role service to.

The CA database and log files must be located on shared storage. Specify the shared storage location during step 12 of the CA installation procedure.

To verify shared storage is online

1. Log on to the destination server.
2. Start Server Manager.
3. In the console tree, double-click **Storage**, and click **Disk Management**.
4. Ensure that the shared storage is online and assigned to the node you are logged on to.

Importing the CA certificate

If you are adding the CA role service by using Server Manager, you must complete the following procedure to import the CA certificate.

To import the CA certificate

1. Start the Certificates snap-in for the local computer account.
2. In the console tree, double-click **Certificates (Local Computer)**, and click **Personal**.

3. On the **Action** menu, click **All Tasks**, and then click **Import** to open the Certificate Import Wizard. Click **Next**.
4. Locate the <*CAName*>.p12 file created by the CA certificate and private key backup on the source CA, and click **Open**.
5. Type the password, and click **OK**.
6. Click **Place all certificates in the following store**.
7. Verify **Personal** is displayed in **Certificate store**. If it is not, click **Browse**, click **Personal**, click **OK**.

   Note
   If you are using a network HSM, complete steps 8 through 10 to repair the association between the imported CA certificate and the private key that is stored in the HSM. Otherwise, click **Finish** to complete the wizard and click **OK** to confirm that the certificate was imported successfully.
8. In the console tree, double-click **Personal Certificates**, and click the imported CA certificate.
9. On the **Action** menu, click **Open**. Click the **Details** tab, copy the serial number to the Clipboard, and then click **OK**.
10. Open a Command Prompt window, type **certutil –repairstore My "{Serialnumber}"** and then press ENTER.

Adding the CA role service by using Server Manager

If your destination server is a domain member, you must use an account that is a member of the Domain Admins or Enterprise Admins group in order for the installation wizard to access objects in AD DS.

Important
If you made a backup CAPolicy.inf file from the source CA, review the settings and make adjustments, if necessary. Copy the CAPolicy.inf file to the %windir% folder (C:\Windows by default) of the destination CA before adding the CA role service.

To add the CA role service by using Server Manager

1. Log on to the destination server, and start Server Manager.
2. In the console tree, click **Roles**.
3. On the **Action** menu, click **Add Roles**.
4. If the **Before you Begin** page appears, click **Next**.
5. On the **Select Server Roles** page, select the **Active Directory Certificate Services** check box, and click **Next**.
6. On the **Introduction to AD CS** page, click **Next**.
7. On the **Role Services** page, click the **Certification Authority** check box, and click **Next**.

   Note

If you plan to install other role services on the destination server, you should complete the CA installation first, and then install other role services separately. Installation procedures for other AD CS role services are not described in this guide.

8. On the **Specify Setup Type** page, specify either **Enterprise** or **Standalone**, to match the source CA, and click **Next**.
9. On the **Specify CA Type** page, specify either **Root CA** or **Subordinate CA**, to match the source CA, and click **Next**.
10. On the **Set Up Private Key** page, select **Use existing private key** and **Select a certificate and use its associated private key**.

    Note
    If an HSM is used by the CA, select the private key by following procedures provided by the HSM vendor.

11. In the **Certificates** list, click the imported CA certificate, and then click **Next**.

    Note
    If you are using a custom CSP that requires strong private key protection, click **Allow administrator interaction when the private key is accessed by the CA**. The CSPs included with Windows Server do not require this setting to be enabled.

12. On the **CA Database** page, specify the locations for the CA database and log files.

    Note
    If you are migrating the CA to a failover cluster, the specified locations for database and log files must be on shared storage that is attached to all nodes. Because the location is common to cluster nodes, click **Yes** to overwrite the existing CA database as you add the CA role service to other nodes.

    Important
    If you specify locations that are different from the locations used on the source CA, then you must also edit the registry settings backup file before the CA is restored. If the locations specified during setup are different from the locations specified in the registry settings, the CA cannot start.

13. On the **Confirmation** page, review the messages, and then click **Configure**.
14. If you are migrating to a failover cluster, stop the Active Directory Certificate Services service (Certsvc) and HSM service if your CA uses an HSM. Then repeat the procedures to import the CA certificate and add the CA role service on other cluster nodes.

Adding the CA role service by using Windows PowerShell

Use the following procedure to add the CA role service by using the Install-ADCSCertificateAuthority cmdlet with the ExistingCertificateParameterSet:

```
Install-AdcsCertificationAuthority [-AllowAdministratorInteraction [<SwitchParameter>]]
[-CAType <CAType>]
[-CertFile <String>] [-CertFilePassword <SecureString>] [-CertificateID <String>] [-
Credential <PSCredential>]
[-DatabaseDirectory <String>] [-Force [<SwitchParameter>]] [-LogDirectory <String>] [-
OverwriteExistingDatabase
[<SwitchParameter>]] [-OverwriteExistingKey [<SwitchParameter>]] [-Confirm
[<SwitchParameter>]] [-WhatIf
[<SwitchParameter>]] [<CommonParameters>]
```

The ExistingCertificateParameterSet is the preferred for migration because you can use the `-CertificateID` parameter to identify the CA certificate from the Importing the CA certificate section in order to configure for the CA. The value for `-CertificateID` can be either the thumbprint or the serial number of the imported certificate.

To add the CA role service by using Windows PowerShell

1. Right-click **Windows PowerShell** and click **Run as Administrator**.
2. To install the CA role service binaries with the Certification Authority and Certificate Templates MMC tools, type the following command and press ENTER:

   ```
   Add-WindowsFeature ADCS-Cert-Authority -
   IncludeManagementTools
   ```

3. Type the `Install-AdcsCertificationAuthority` cmdlet with the appropriate parameters and press ENTER. For example, to restore an Enterprise Subordinate CA by using the certificate you imported in the Importing the CA certificate section, type the following command and press ENTER:

   ```
   Install-AdcsCertificationAuthority –CAType
   EnterpriseSubordinateCA –CertificateID "YourCertSerialNumber
   or YourCertThumbprint" –credential (get-credential
   domain\administrator)
   ```

   Type the password for a member of the Enterprise Admins group or Domain Admins group as needed.

For more information about using Windows PowerShell to install other AD CS role services, see Deploying AD CS Using Windows PowerShell. For more general information about Windows PowerShell cmdlets for AD CS, see AD CS Deployment Cmdlets in Windows PowerShell.

Restoring the CA database and configuration on the destination server

The procedures in this section should be completed only after the CA role service has been installed on the destination server.

If you are migrating to a failover cluster, add the CA role service to all cluster nodes before restoring the CA database. The CA database should be restored on only one cluster node and must be located on shared storage.

Restoring the source CA backup includes the following tasks:

- Restoring the source CA database on the destination server
- Restoring the source CA registry settings on the destination server
- Verifying certificate extensions on the destination CA
- Restoring the certificate templates list (required only for enterprise CAs)

Restoring the source CA database on the destination server

This section describes two different procedures for restoring the source CA database backup on the destination server.

If you are migrating to a Server Core installation, you must use the procedure "To restore the CA database by using Certutil.exe" or "To restore the CA database by using Windows PowerShell." In general, it is possible to remotely manage a CA running on a Server Core installation by using the Certification Authority snap-in and Server Manager; however, it is only possible to restore a CA database remotely by using Windows PowerShell.

If you are migrating to a failover cluster, ensure that shared storage is online and restore the CA database on only one cluster node.

To restore the CA database by using the Certification Authority snap-in

1. Log on to the destination server by using an account that is a CA administrator.
2. Start the Certification Authority snap-in.
3. Right-click the node with the CA name, point to **All Tasks**, and then click **Restore CA**.
4. On the **Welcome** page, click **Next**.
5. On the **Items to Restore** page, select **Certificate database and certificate database log**.
6. Click **Browse**. Navigate to the parent folder that holds the **Database** folder (the folder that contains the CA database files created during the CA database backup).

   Caution
   Do not select the **Database** folder. Select its parent folder.
7. Click **Next** and then click **Finish**.
8. Click **Yes** to start the CA service (certsvc).

To restore only the CA database by using Windows PowerShell

1. Log on to the destination server by using an account that is a CA administrator.
2. Right-click **Windows PowerShell** and click **Run as Administrator**.
3. Type the following command to stop the CA service and press ENTER:

```
Stop-service certsvc
```

4. Type the following command and press ENTER:

```
Restore-CARoleService –path < CA Database Backup Directory> -
DatabaseOnly - Force
```

> **Note**
> The value of <*CA Database Backup Directory*> is the parent directory of the **Database** directory. For example, if the CA database backup files are located in C:\Temp\Database, then the value of <*CA Database Backup Directory*> is C:\Temp. Include the force flag because an empty CA database will already be present after you perform the steps in Adding the CA role service by using Server Manager.

5. Type the following command to restart the CA service and press ENTER:

```
Start-service certsvc
```

To restore the only CA database by using Certutil.exe

1. Log on to the destination server by using an account that is a CA administrator.
2. Open a Command Prompt window.
3. Type the following command to stop the CA service and press ENTER:

```
Net stop certsvc
```

4. Type **certutil.exe -f -restoredb** <*CA Database Backup Directory*> and press ENTER.

> **Note**
> The value of <*CA Database Backup Directory*> is the parent directory of the **Database** directory. For example, if the CA database backup files are located in C:\Temp\Database, then the value of <*CA Database Backup Directory*> is C:\Temp.

5. Type the following command to restart the CA service and press ENTER:

```
Net start certsvc
```

Restoring the source CA registry settings on the destination server

The CA configuration information is stored in the registry in:
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CertSvc

Before importing the registry settings from the source CA to the target CA, create a backup of the default target CA registry configuration by using the procedure Backing up CA registry settings. Be sure to perform these steps on the target CA and to name the registry file a name such as "DefaultRegCfgBackup.reg" to avoid confusion.

Important
Some registry parameters should be migrated without changes from the source CA computer, and some should not be migrated. If they are migrated, they should be updated in the target system after migration because some values are associated with the CA itself, whereas others are associated with the domain environment, the physical host, the Windows version, or other factors that may be different in the target system.

A suggested way of performing the registry configuration import is first to open the registry file you exported from the source CA in a text editor and analyze it for settings that may need to be changed or removed. The following table shows the configuration parameters that should be transferred from the source CA to the target CA.

Registry location	Configuration parameter
HKEY_LOCAL_MACHINE\system\currentcontrolset\services\certsvc\Configuration	LDAPFlags
HKEY_LOCAL_MACHINE\system\currentcontrolset\services\certsvc\Configuration*CAname*	DSConfigDN ForceTeletex CRLEditFlags CRLFlags InterfaceFlags (required only if has been changed manually) EnforceX500NameLengths SubjectTemplate ValidityPeriod ValidityPeriodUnits KRACertHash

Registry location	Configuration parameter
	KRACertCount KRAFlags CRLPublicationURLs CRLPeriod CRLPeriodUnits CRLOverlapPeriod CRLOverlapUnits CRLDeltaPeriod CRLDeltaPeriodUnits CRLDeltaOverlapPeriod CRLDeltaOverlapUnits CACertPublicationURLs (check for custom entries with hard-coded host names or other data specific to the source CA) CACertHash
HKEY_LOCAL_MACHINE\system\currentcontrolset\services\certsvc\Configuration*CAname*\ExitModules\CertificateAuthority_MicrosoftDefault.Exit	PublishCertFlags
HKEY_LOCAL_MACHINE\system\currentcontrolset\services\certsvc\Configuration*CAname*\PolicyModules\CertificateAuthority_MicrosoftDefault.Policy	EnableRequestExtensionList EnableEnrolleeRequestExtensionList DisableExtensionList SubjectAltName SubjectAltName2 RequestDispositio

Registry location	Configuration parameter
	n EditFlags

To analyze the registry file

1. Right-click the .reg text file created by exporting the settings from the source CA.
2. Click **Edit** to open the file in a text editor.
3. If the target CA's computer name is different from the source CA's computer name, search the file for the host name of the source CA computer. For each instance of the host name found, ensure that it is the appropriate value for the target environment. Change the host name, if necessary. Update the **CAServerName** value.

   Important
   If the host name is located in the .reg file as part of the CA name, such as in the **Active** value within the **Configuration** key or the **CommonName** value within the **CAName** key, do not change the setting. The CA name must not be changed as part of the migration. This means the new target CA must have the old CA's name, even if part of that name is the old CA's host name.
4. Check any registry values that indicate local file paths, such as the following, to ensure drive letter names and paths are correct for the target CA. If there is a mismatch between the source and the target CA, either update the values in the file or remove them from the file so that the default settings are preserved on the target CA.

   These storage location settings are elected during CA setup. They exist under the Configuration registry key:

   - DBDirectory
   - DBLogDirectory
   - DBSystemDirectory
   - DBTempDirectory

   The following settings under the Configuration\{*CA Name*} registry key contain, in their default values, a local path. (Alternatively, you can update these values after importing them by using the Certification Authority snap-in. The values are located on the CA properties **Extensions** tab.)

   - CACertPublicationURLs
   - CRLPublicationURLs

Warning

Some registry values are associated with the CA, while others are associated with the domain environment, the physical host computer, the Windows version, or even other role services. Consequently, some registry parameters should be migrated without

changes from the source CA computer and others should not. Any value that is not listed in the .reg text file that is restored on the target CA retains its existing setting or default value. An issue that can occur, if the registry values are not properly verified, is explained in the following TechNet Wiki article: AD: Certification Authority Web Enrollment Configuration Failed 0x80070057 (WIN32: 87).

Remove any registry values that you do not want to import into the target CA. Once the .reg text file is edited, it can be imported into the target CA. By importing the source server registry settings backup into the destination server, the source CA configuration is migrated to the destination server.

To import the source CA registry backup on the destination CA

1. Log on to the destination server as a member of the local Administrators group.
2. Open a Command Prompt window.
3. Type **net stop certsvc** and press ENTER.
4. Type **reg import** *<Registry Settings Backup.reg>* and press ENTER.

To edit the CA registry settings

1. Click **Start**, type **regedit.exe** in the **Search programs and files** box, and press ENTER to open the Registry Editor.
2. In the console tree, locate the key `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\CertSvc\Configuration`, and click **Configuration**.
3. In the details pane, double-click **DBSessionCount**.
4. Click **Hexadecimal**. In **Value data**, type **64**, and then click **OK**.
5. Verify the locations specified in the following settings are correct for your destination server, and change them as needed to indicate the location of the CA database and log files.
   - DBDirectory
   - DBLogDirectory
   - DBSystemDirectory
   - DBTempDirectory

   Important
   Complete steps 6 through 8 only if the name of your destination server is different from the name of your source server.
6. In the console tree of the registry editor, expand **Configuration**, and click your CA name.
7. Modify the values of the following registry settings by replacing the source server name with the destination server name.

   Note
   In the following list, CACertFileName and ConfigurationDirectory values are

created only when certain CA installation options are specified. If these two settings are not displayed, you can proceed to the next step.

- CAServerName
- CACertFileName
- ConfigurationDirectory – This value should appear in Windows Registry under the following location:
  `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\CertSvc\Configuration`.

Verifying certificate extensions on the destination CA

The steps described for importing the source CA registry settings and editing the registry in case of a server name change are intended to retain the network locations that were used by the source CA to publish CRLs and CA certificates. If the source CA was published to default Active Directory locations, after completing the previous procedure, there should be an extension with publishing options enabled and an LDAP URL that references the source server's NetBIOS name; for example,

`ldap:///CN=<CATruncatedName><CRLNameSuffix>,CN=<ServerShortName>,CN=CDP,CN=Public Key Services,CN=Services,<ConfigurationContainer><CDPObjectClass>`.

Because many administrators configure extensions that are customized for their network environment, it is not possible to provide exact instructions for configuring CRL distribution point and authority information access extensions.

Carefully review the configured locations and publishing options, and ensure that the extensions are correct according to your organization's requirements.

To verify extensions by using the Certification Authority snap-in

1. Review and modify the CRL distribution point and authority information access extensions and publishing options by following example procedures described in Specify CRL Distribution Points (http://go.microsoft.com/fwlink/?LinkID=145848).
2. If the destination server name is different from the source server name, add an LDAP URL specifying a location that references the destination server's NetBIOS name with the substitution variable <*ServerShortName*>; for example
   `ldap:///CN=<CATruncatedName><CRLNameSuffix>,CN=<ServerShortName>,CN=CDP,CN=Public Key Services,CN=Services,<ConfigurationContainer><CDPObjectClass>`.
3. Ensure that the CDP options are set so that the former CDP location is not included in the CDP extension of newly issued certificates or in the Freshest CRL extension of CRLs.

Restoring the certificate templates list

The following procedure is required only for an enterprise CA. A standalone CA does not have certificate templates.

To assign certificate templates to the destination CA

1. Log on with administrative credentials to the destination CA.
2. Open a command prompt window.
3. Type **certutil -setcatemplates +** <*templatelist*> and press ENTER.

   Note
   Replace <*templatelist*> with a comma-separated list of the template names that are listed in the catemplates.txt file created during the procedure "To record a CA templates list by using Certutil.exe." For example, **certutil -setcatemplates +Administrator,User,DomainController**. Review the list of templates created during Backing up a CA templates list.

Granting permissions on AIA and CDP containers

If the name of the destination server is different from the source server, the destination server must be granted permissions on the source server's CDP and AIA containers in AD DS to publish CRLs and CA certificates. Complete the following procedure in the case of a server name change.

To grant permissions on the AIA and CDP containers

1. Log on as a member of the Enterprise Admins group to a computer on which the Active Directory Sites and Services snap-in is installed. Open Active Directory Sites and Services (dssite.msc).
2. In the console tree, click the top node.
3. On the **View** menu, click **Show services node**.
4. In the console tree, expand **Services**, expand **Public Key Services**, and then click **AIA**.
5. In the details pane, right-click the name of the CA, and then click **Properties**.
6. Click the **Security** tab, and then click **Add**.
7. Click **Object Types**, click **Computers**, and then click **OK**.
8. Type the name of the CA, and click **OK**.
9. In the **Allow** column, click **Full Control**, and click **Apply**.
10. The previous CA computer object is displayed (as **Account Unknown** with a security identifier following it) in **Group or user names**. You can remove that account. To do so, select it and then click **Remove**. Click **OK**.
11. In the console tree, expand **CDP**, and then click the folder with the same name as the CA.
12. In the details pane, right-click the **cRLDistributionPoint** item at the top of the list, and then click **Properties**.
13. Click the **Security** tab, and then click **Add**.
14. Click **Object Types**, click **Computers**, and then click **OK**.
15. Type the name of the destination server, and click **OK**.
16. In the **Allow** column, click **Full Control**, and click **Apply**.

17. The previous CA computer object is displayed (as **Account Unknown** with a security identifier following it) in **Group or user names**. You can remove that account. To do so, select it and then click **Remove**. Click **OK**.
18. Repeat steps 13 through 18 for each **cRLDistributionPoint** item.

Notes

If you are using file//\\computer\share syntax in the CDP Extensions for publishing the CRL to a shared folder location, then you may need to adjust the permissions to that shared folder so that the destination CA has the ability to write to that location.

If you are hosting the CDP on the destination server and using a AIA or CDP path that includes an alias name (for example, pki.contoso.com) for the destination, you may need to adjust the DNS record so that it points to the correct destination IP address.

Additional procedures for failover clustering

If you are migrating to a failover cluster, complete the following procedures after the CA database and registry settings have been migrated to the destination server.

- Configuring failover clustering for the destination CA
- Granting permissions on public key containers
- Editing the DNS name for a clustered CA in AD DS
- Configuring CRL distribution points for failover clusters

Note

Migration of a CA to a failover cluster running on the Server Core installation option of Windows Server 2008 R2 is not described in this guide.

Configuring failover clustering for the destination CA

If you are migrating to a failover cluster, complete the following procedures to configure failover clustering for AD CS.

To configure AD CS as a cluster resource

1. Click **Start**, point to **Run**, type **Cluadmin.msc**, and then click **OK**.
2. In the console tree of the Failover Cluster Management snap-in, click **Services and Applications**.
3. On the **Action** menu, click **Configure a service or Application**. If the **Before you begin** page appears, click **Next**.
4. In the list of services and applications, select **Generic Service**, and click **Next**.
5. In the list of services, select **Active Directory Certificate Services**, and click **Next**.
6. Specify a service name, and click **Next**.
7. Select the disk storage that is still mounted to the node, and click **Next**.
8. To configure a shared registry hive, click **Add**, type

SYSTEM\CurrentControlSet\Services\CertSvc, and then click **OK**. Click **Next** twice.

9. Click **Finish** to complete the failover configuration for AD CS.
10. In the console tree, double-click **Services and Applications**, and select the newly created clustered service.
11. In the details pane, click **Generic Service**. On the **Action** menu, click **Properties**.
12. Change **Resource Name** to **Certification Authority**, and click **OK**.

If you use a hardware security module (HSM) for your CA, complete the following procedure.

To create a dependency between a CA and the network HSM service

1. Open the Failover Cluster Management snap-in. In the console tree, click **Services and Applications**.
2. In the details pane, select the previously created name of the clustered service.
3. On the **Action** menu, click **Add a resource**, and then click **Generic Service**.
4. In the list of available services displayed by the **New Resource** wizard, click the name of the service that was installed to connect to your network HSM. Click **Next** twice, and then click **Finish**.
5. Under **Services and Applications** in the console tree, click the name of the clustered services.
6. In the details pane, select the newly created **Generic Service**. On the **Action** menu, click **Properties**.
7. On the **General** tab, change the service name if desired, and click **OK**. Verify that the service is online.
8. In the details pane, select the service previously named **Certification Authority**. On the **Action** menu, click **Properties**.
9. On the **Dependencies** tab, click **Insert**, select the network HSM service from the list, and click **OK**.

Granting permissions on public key containers

If you are migrating to a failover cluster, complete the following procedures to grant all cluster nodes permissions to on the following AD DS containers:

- The AIA container
- The Enrollment container
- The KRA container

To grant permissions on public key containers in AD DS

1. Log on to a domain member computer as a member of the Domain Admins group or Enterprise Admins group.
2. Click **Start**, point to **Run**, type **dssite.msc**, and then click **OK**.

3. In the console tree, click the top node.
4. On the **View** menu, click **Show services node**.
5. In the console tree, expand **Services**, then **Public Key Services**, and then click **AIA**.
6. In the details pane, right-click the name of the source CA, and then click **Properties**.
7. Click the **Security** tab, and then click **Add**.
8. Click **Object Types**, click **Computers**, and then click **OK**.
9. Type the computer account names of all cluster nodes, and click **OK**.
10. In the **Allow** column, select the **Full Control** check box next to each cluster node, and click **OK**.
11. In the console tree, click **Enrollment Services**.
12. In the details pane, right-click the name of the source CA, and then click **Properties**.
13. Click the **Security** tab, and then click **Add**.
14. Click **Object Types**, click **Computers**, and then click **OK**.
15. Type the computer account names of all cluster nodes, and click **OK**.
16. In the **Allow** column, select the **Full Control** check box next to each cluster node, and click **OK**.
17. In the console tree, click **KRA**.
18. In the details pane, right-click the name of the source CA, then click **Properties**.
19. Click the **Security** tab, and then click **Add**.
20. Click **Object Types**, click **Computers**, and then click **OK**.
21. Type the names of all cluster nodes, and click **OK**.
22. In the **Allow** column, select the **Full Control** check box next to each cluster node, and click **OK**.

Editing the DNS name for a clustered CA in AD DS

When the CA service was installed on the first cluster node, the Enrollment Services object was created and the DNS name of that cluster node was added to the dNSHostName attribute of the Enrollment Services object. Because the CA must operate on all cluster nodes, the value of the dNSHostName attribute of the Enrollment Services object must be the service name specified in step 6 of the procedure "To configure AD CS as a cluster resource."

If you are migrating to a clustered CA, complete the following procedure on the active cluster node. It is necessary to complete the procedure on only one cluster node.

To edit the DNS name for a clustered CA in AD DS

1. Log on to the active cluster node as a member of the Enterprise Admins group.
2. Click **Start**, point to **Run**, type **adsiedit.msc**, and then click **OK**.
3. In the console tree, click **ADSI Edit**.
4. On the **Action** menu, click **Connect to**.
5. In the list of well-known naming contexts, click **Configuration**, and click **OK**.

6. In the console tree, expand **Configuration**, **Services**, and **Public Key Services**, and click **Enrollment Services**.
7. In the details pane, right-click the name of the cluster CA, and click **Properties**.
8. Click **dNSHostName**, and click **Edit**.
9. Type the service name of the CA as displayed under **Failover Cluster Management** in the Failover Cluster Manager snap-in, and click **OK**.
10. Click **OK** to save changes.

Configuring CRL distribution points for failover clusters

In a CA's default configuration, the server's short name is used as part of the CRL distribution point and authority information access locations.

When a CA is running on a failover cluster, the server's short name must be replaced with the cluster's short name in the CRL distribution point and authority information access locations. To publish the CRL in AD DS, the CRL distribution point container must be added manually.

Important
The following procedures must be performed on the active cluster node.

To change the configured CRL distribution points

1. Log on to the active cluster node as a member of the local Administrators group.
2. Click **Start**, click **Run**, type **regedit**, and then click **OK**.
3. Locate the registry key **\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CertSvc\Configuration**.
4. Click the name of the CA.
5. In the right pane, double-click **CRLPublicationURLs**.
6. In the second line, replace **%2** with the service name specified in step 6 of the procedure "To configure AD CS as a cluster resource."

   Tip
   The service name also appears in the Failover Cluster Management snap-in under **Services and Applications**.
7. Restart the CA service.
8. Open a command prompt, type **certutil -CRL**, and press ENTER.

   Note
   If a "Directory object not found" error message is displayed, complete the following procedure to create the CRL distribution point container in AD DS.

To create the CRL distribution point container in AD DS

1. At a command prompt, type **cd %windir%\System32\CertSrv\CertEnroll**, and press

ENTER. The CRL file created by the certutil –CRL command should be located in this directory.

2. To publish the CRL in AD DS, type **certutil -f -dspublish** *"CRLFile.crl"* and press ENTER.

Next steps

After completing the procedures to migrate the CA, you should complete the procedures described in Verifying the Certification Authority Migration.

See also

- Active Directory Certificate Services Migration Guide for Windows Server 2012 R2
- Prepare to Migrate
- Verifying the Certification Authority Migration
- Post-Migration Tasks
- Migrating Roles and Features in Windows Server

Verifying the Certification Authority Migration

Complete the following procedures to verify the operation of the destination certification authority (CA).

- Verifying certificate enrollment
- Verifying CRL publishing

Verifying certificate enrollment

To verify migration to an enterprise CA, complete the procedure Request a Certificate (http://go.microsoft.com/fwlink/?LinkId=179367).

You can start autoenrollment for user certificates by completing the following procedure or by running the following command: **certutil.exe -pulse**.

To verify autoenrollment

1. Log on to a domain member computer by using an account that has Autoenroll, Enroll, and Read permissions for the certificate templates that are assigned to the destination CA.
2. Click **Start**, and then click **Run**.
3. Type **certmgr.msc**, and then click **OK** to open the Certificates snap-in.
4. In the console tree, right-click **Certificates – Current User**, click **All Tasks**, and then click **Automatically Enroll and Retrieve Certificates** to start the Certificate Enrollment

wizard.

5. On the **Before You Begin** page, click **Next**.
6. On the **Request Certificates** page, a list of one or more certificate templates should be displayed. Select the check box next to each certificate template that you want to request, and then click **Enroll**.

   Note
   If the correct certificate templates are not displayed, click **Show all templates** to display all certificate templates that are assigned to the issuing CA. A status of **Unavailable** indicates the user account does not have permission to autoenroll for a certificate. Follow the steps in the "To configure certificate templates for autoenrollment" procedure earlier in this topic.
7. Click **Finish** to complete the enrollment process.
8. In the console tree, double-click **Personal**, and then click **Certificates** to display a list of installed user certificates and to verify that the certificate that you requested is displayed.

To verify migration to a standalone CA, complete the following procedure.

To verify manual enrollment by using Certreq.exe

1. Create a certificate request, and save it to a file by completing the procedure Create a Custom Certificate Request (http://go.microsoft.com/fwlink/?LinkId=179368).
2. Open a Command Prompt window.
3. Type **certreq -submit -config "<DestinationServerName\CAName>" "<CertificateRequestInput>" "<CertificateResponseOutput>"** and press ENTER.

   Note
   If a message is displayed indicating that the certificate request is pending, the certificate must be issued by a certificate manager or CA administrator by using the Certification Authority snap-in. After the certificate is issued, it must be retrieved by using the command in step 4. If the certificate is issued immediately by the CA, the file specified in <CertificateResponseOutput> contains the certificate. Use the command in step 5 to install the certificate into the certificate store.
4. Type **certreq –retrieve -config "<DestinationServerName\CAName>" <RequestID> <CertificateResponseOutput>** and press ENTER.
5. Type **certreq –accept -config "<DestinationServerName\CAName>" <CertificateResponseOutput>** and press ENTER.

Option	Description	Example
-config	The –config option is followed by a string specifying a host name and CA name in the	Certreq.exe –submit –config Server1\CA1 C:\RequestFile.txt

Option	Description	Example
	format HostName\CAName.	C:\ResponseFile.cer
DestinationServerName	The host name of the destination server.	
CAName	The CA name being migrated.	
CertificateRequestInput	The path and name of the file containing the certificate request that was created by using the procedure "Create a Custom Certificate Request."	
CertificateResponseOutput	The path and name of the file receiving the issued certificate from the CA. If the certificate request is pending, the file contains a message from the CA indicating the status of the request and the request ID. The request ID is used to retrieve the certificate after it is issued by a certificate manager or CA administrator.	

Verifying CRL publishing

If you published a certificate revocation list (CRL) with an extended validity period before beginning migration, you should change the CRL publishing period back to its pre-migration value by completing the procedure Schedule the publication of the certificate revocation list.

Manually publish a CRL by completing one of the procedures described in Manually Publish a CRL.

Next steps

After completing verification steps, you should review the topic Post-Migration Tasks and complete the procedures appropriate for your environment.

- Active Directory Certificate Services Migration Guide for Windows Server 2012 R2
- Prepare to Migrate
- Migrating the Certification Authority
- Post-Migration Tasks
- Migrating Roles and Features in Windows Server

Post-Migration Tasks

Post-migration steps can be performed after migration has been completed and the operation of the destination CA has been verified.

If verification steps have failed, review the Troubleshooting section in this topic.

- Upgrading certificate templates in Active Directory Domain Services (AD DS)
- Retrieving certificates after a host name change
- Restoring Active Directory Certificate Services (AD CS) to the source server in the event of migration failure
- Troubleshooting migration

Upgrading certificate templates in Active Directory Domain Services (AD DS)

Review the post-migration steps below and perform only those that are appropriate for your environment and migration scenario.

The following additional default certificate templates are included in enterprise certification authorities (CAs) running on Windows Server 2012 R2, Windows Server 2012, Windows Server 2008 R2 and Windows Server 2008 but are not included in Windows Server 2003:

- OCSP Response Signing
- Kerberos Authentication

These certificate templates are not required for CA operation. OCSP Response Signing certificates are required if you are deploying the Online Responder role service.

If you require these additional certificate templates, complete the following procedure.

To upgrade certificate templates in AD DS by using the Certificate Templates snap-in

1. Log on to the destination server as a member of the Enterprise Admins group.
2. Open the Certificate Templates snap-in. The snap-in automatically adds the default certificate templates to AD DS.

Retrieving certificates after a host name change

If the destination server name is different from the source server name, you might need to manually retrieve any certificates that were issued by the source CA and had not been retrieved before migration.

Complete this procedure on the computer that was used to submit the certificate request to the source CA.

To retrieve a certificate by using Certreq.exe

1. Open a Command Prompt window.
2. Type **certreq –retrieve -config "<DestinationServerName\CAName>" <RequestID> <CertificateResponseOutput>** and press ENTER.
3. Type **certreq –accept <CertificateResponseOutput>** and press ENTER.

Option	Description	Example
-config	The –config option is followed by a string specifying a host name and CA name in the format HostName\CAName.	Certreq.exe –submit –config Server1\CA1 C:\RequestFile.txt C:\ResponseFile.cer
DestinationServerName	The host name of the destination server.	
CAName	The CA name being migrated.	
CertificateRequestInput	The path and name of the file containing the certificate request that was created by using the procedure "Create a Custom Certificate Request."	
CertificateResponseOutput	The path and name of the file receiving the issued certificate from the CA. If the certificate request is pending, the file contains a message from the CA indicating the status of the request and the request ID. The request ID is used to retrieve the certificate after it is issued by a certificate manager or CA administrator.	
RequestID	The Request ID value returned	

Option	Description	Example
	by a CA in response to a certificate request. The Request ID value is displayed in command output and written to the CertificateResponseOutput file.	

Restoring Active Directory Certificate Services (AD CS) to the source server in the event of migration failure

If you removed the CA role service from the source server as described in the procedure Removing the CA role service from the source server, you can restore the source CA by reinstalling the CA role service on the source server. It is important to remove the CA role service from the destination server before reinstalling the CA role service on the source server.

If you did not remove the CA role service from the source server, you should not remove the CA role service from the destination server. Simply shut down the destination CA and start the source CA.

Rollback procedures can be completed in less than one hour.

To remove the CA role service from the destination server, use the Remove Roles Wizard in Server Manager.

To add the CA role service to a source server running Windows Server 2003, use the Add/Remove Windows Components wizard.

To add the CA role service to a source server running Windows Server 2008 or later, use the Add Roles Wizard in Server Manager.

Troubleshooting migration

If you encounter errors during verification procedures, use Event Viewer to review the Application log on the destination CA. View an Error event in the preview pane or event properties, and click **Event Log Online Help** to open a Web page with troubleshooting procedures for that event.

For the full collection of documented AD CS events, see AD CS Events and Errors.

Migrating Active Directory Federation Services Role Service to Windows Server 2012 R2

About this guide

This guide provides instructions to migrate the following role services to Active Directory Federation Services (AD FS) that is installed with Windows Server® 2012 R2:

- AD FS 2.0 federation server installed on Windows Server 2008 or Windows Server 2008 R2
- AD FS federation server installed on Windows Server 2012

Target audience

- IT architects who are responsible for computer management and security throughout an organization
- IT operations engineers who are responsible for the day-to-day management and troubleshooting of networks, servers, client computers, operating systems, or applications
- IT operations managers who are accountable for network and server management

Supported migration scenarios

The migration instructions in this guide consist of the following tasks:

- Exporting the AD FS 2.0 configuration data from your server that is running Windows Server 2008, Windows Server 2008 R2, or Windows Server 2012
- Performing an in-place upgrade of the operating system of this server from Windows Server 2008, Windows Server 2008 R2 or Windows Server 2012 to Windows Server® 2012 R2
- Recreating the original AD FS configuration and restoring the remaining AD FS service settings on this server, which is now running the AD FS server role that is installed with Windows Server® 2012 R2.

This guide does not include instructions to migrate a server that is running multiple roles. If your server is running multiple roles, we recommend that you design a custom migration process specific to your server environment, based on the information provided in other role migration guides. Migration guides for additional roles are available on the Windows Server Migration Portal.

Supported operating systems

Source server processor	Source server operating system	Destination server operating system	Destination server processor
x86- or x64-based	Windows Server 2008, both full and Server Core installation options	Windows Server® 2012 R2 (Server Core and full installation options)	x64-based
x64-based	Windows Server 2008 R2		
x64-based	Server Core installation option of Windows Server 2008 R2		
x64-based	Server Core and full installation options of Windows Server 2012		

Notes

- The versions of operating systems that are listed in the preceding table are the oldest combinations of operating systems and service packs that are supported.
- The Foundation, Standard, Enterprise, and Datacenter editions of the Windows Server operating system are supported as the source or the destination server.
- Migrations between physical operating systems and virtual operating systems are supported.

Supported AD FS role services and features

The following table describes the migration scenarios of the AD FS role services and their respective settings that are described in this guide.

From	To AD FS installed with Windows Server® 2012 R2
AD FS 2.0 federation server installed on Windows Server 2008 or Windows Server 2008 R2	Migration on the same server is supported. For more information, see: • Preparing to Migrate the AD FS Federation Server • Migrating the AD FS Federation Server
AD FS federation server installed on Windows Server 2012	Migration on the same server is supported. For more information see: • Preparing to Migrate the AD FS Federation Server • Migrating the AD FS Federation Server

Verifying the AD FS Migration to Windows Server 2012 R2

Preparing to Migrate the AD FS Federation Server

To perform the same server migration of your AD FS federation server farm for Windows Server 2012 R2, you must review the following information:

Note
The information below applies to migrating a one-node federation server, as well as a WID or a SQL Server federation server farm. It applies to the migration of a federation server running AD FS 2.0 running on Windows Server 2008 or Windows Server 2008 R2 or AD FS installed with Windows Server 2012.

- Migration Process Outline
- New AD FS functionality in Windows Server 2012 R2
- AD FS Requirements in Windows Server 2012 R2
- Increasing your Windows PowerShell limits
- Other migration tasks and considerations

Migration Process Outline

To complete the migration of your AD FS federation server farm to Windows Server 2012 R2, you must complete the following tasks:

1. Export, record, and backup the following configuration data in your existing AD FS farm. For detailed instructions on how to complete these tasks, see Migrating the AD FS Federation Server.

   The following settings are migrated with the scripts located in the \support\adfs folder on the Windows Server 2012 R2 installation CD:

   - Claims provider trusts, with the exception of custom claim rules on the Active Directory Claims provider trust. For more information, see Migrating the AD FS Federation Server.
   - Relying party trusts.
   - AD FS internally generated, self-signed token signing and token decryption certificates.

   Any of the following custom settings must be migrated manually:

- Service settings:
  - Non-default token signing and token decryption certificates that were issued by an enterprise or public certification authority.
  - The SSL server authentication certificate used by AD FS.
  - The service communications certificate used by AD FS (by default, this is the same certificate as the SSL certificate.
  - Non-default values for any federation service properties, such as AutoCertificateRollover or SSO lifetime.
  - Non-default AD FS endpoint settings and claim descriptions.
- Custom claim rules on the Active Directory claims provider trust.
- AD FS sign-in page customizations

For more information, see Migrating the AD FS Federation Server.

2. Create a Windows Server 2012 R2 federation server farm.
3. Import the original configuration data into this new Windows Server 2012 R2 AD FS farm.
4. Configure and customize the AD FS sign-in pages.

New AD FS functionality in Windows Server 2012 R2

The following AD FS functionality changes in Windows Server 2012 R2 impact a migration from AD FS 2.0 or AD FS in Windows Server 2012:

- **IIS dependency**

  AD FS in Windows Server 2012 R2 is self-hosted and does not require IIS installation. Make sure you note the following as a result of this change:

  - SSL certificate management for both federation servers and proxy computers in your AD FS farm must now be performed via Windows PowerShell.
- **Changes to AD FS sign-in pages' settings and customizations**

  In AD FS in Windows Server 2012 R2, there are several changes intended to improve the sign-in experience for both administrators and users. The IIS-hosted web pages that existed in the previous version of AD FS are now removed. The look and feel of the AD FS sign-in web pages are self-hosted in AD FS and can now be customized to tailor the user experience. The changes include:

  - Customizing the AD FS sign-in experience, including the customization of the company name, logo, illustration, and sign-in description.
  - Customizing the error messages.
  - Customizing the ADFS Home Realm Discovery experience, which includes the following:
    - Configuring your identity provider to use certain email suffixes.
    - Configuring an identity provider list per relying party.
    - Bypassing Home Realm Discovery for intranet.
    - Creating custom web themes.

For detailed instructions on configuring the look and feel of the AD FS sign-in pages, see Customizing the AD FS Sign-in Pages.

If you have web page customization in your existing AD FS farm that you want to migrate to Windows Server 2012 R2, you can recreate them as part of the migration process using the new customization features in Windows Server 2012 R2.

- **Other changes**
  - AD FS in Windows Server 2012 R2 is based on Windows Identity Foundation (WIF) 3.5, not WIF 4.5. Therefore, some specific features of WIF 4.5 (for example, Kerberos claims and dynamic access control) are not supported in AD FS in Windows Server 2012 R2.
  - Device Registration Service (DRS) in Windows Server 2012 R2 operates on port 443; ClientTLS for user certificate authentication operates on port 49443
    - For active, non-browser clients using certificate transport mode authentication that are specifically hard-coded to point to port 443, a code change is required to continue to use user certificate authentication on port 49443.
    - For passive applications no change is required because AD FS redirects to the correct port for user certificate authentication.
    - Firewall ports between the client and the proxy must enable port 49443 traffic to pass through for user certificate authentication.

AD FS Requirements in Windows Server 2012 R2

In order to successfully migrate your AD FS farm to Windows Server 2012 R2, you must meet the following requirements:

For AD FS to function, each computer that you want to be a federation server must be joined to a domain.

For AD FS running on Windows Server 2012 R2 to function, your Active Directory domain must run either of the following:

- Windows Server 2012 R2
- Windows Server 2012
- Windows Server 2008 R2
- Windows Server 2008

If you plan to use a group Managed Service Account (gMSA) as the service account for AD FS, you must have at least one domain controller in your environment that is running on Windows Server 2012 or Windows Server 2012 R2 operating system.

If you plan to deploy Device Registration Service (DRS) for AD Workplace Join as a part of your AD FS deployment, the AD DS schema needs to be updated to the Windows Server 2012 R2level. There are three ways to update the schema:

1. In an existing Active Directory forest, run adprep /forestprep from the \support\adprep folder of the Windows Server 2012 R2 operating system DVD on any 64-bit server that runs Windows Server 2008 or later. In this case, no additional domain controller needs to be installed, and no existing domain controllers need to be upgraded.

To run adprep/forestprep, you must be a member of the Schema Admins group, the Enterprise Admins group, and the Domain Admins group of the domain that hosts the schema master.

2. In an existing Active Directory forest, install a domain controller that runs Windows Server 2012 R2. In this case, adprep /forestprep runs automatically as part of the domain controller installation.

   During the domain controller installation, you may need to specify additional credentials in order to run adprep /forestprep.

3. Create a new Active Directory forest by installing AD DS on a server that runs Windows Server 2012 R2. In this case, adprep /forestprep does not need to be run because the schema will be initially created with all the necessary containers and objects to support DRS.

SQL Server support for AD FS in Windows Server 2012 R2

If you want to create an AD FS farm and use SQL Server to store your configuration data, you can use SQL Server 2008 and newer versions, including SQL Server 2012.

Increasing your Windows PowerShell limits

If you have more than 1000 claims provider trusts and relying party trusts in your AD FS farm, or if you see the following error while trying to run the AD FS migration export/import tool, you must increase your Windows PowerShell limits:

```
'Exception of type 'System.OutOfMemoryException' was thrown. At
E:\dev\ds\security\ADFSv2\Product\Migration\Export-FederationConfiguration.ps1:176
char:21 + $configData = Invoke-Command -ScriptBlock $GetConfig -Argume ...
```

This error is thrown because the Windows PowerShell session default memory limit is too low. In Windows PowerShell 2.0, the session default memory is 150MB. In Windows PowerShell 3.0, the session default memory is 1024MB. You can verify Windows PowerShell remote session memory limit using the following command: `Get-Item wsman:localhost\Shell\MaxMemoryPerShellMB`. You can increase the limit by running the following command: `Set-Item wsman:localhost\Shell\MaxMemoryPerShellMB 512`.

Other migration tasks and considerations

In order to successfully migrate your AD FS farm to Windows Server 2012 R2, make sure you are aware of the following:

- The migration scripts located in the \support\adfs folder on the Windows Server 2012 R2 installation CD require that you retain the same federation server farm name and service account identity name that you used in your legacy AD FS farm when you migrate it to Windows Server 2012 R2.
- If you want to migrate a SQL Server AD FS farm, note that the migration process involves creating a new SQL database instance into which you must import the original configuration data.

See Also

Migrating Active Directory Federation Services Role Service to Windows Server 2012 R2

Migrating the AD FS Federation Server

To migrate an AD FS federation server that belongs to a single-node AD FS farm, a WIF farm, or a SQL Server farm to Windows Server 2012 R2, you must perform the following tasks:

1. Export and backup the AD FS configuration data
2. Create a Windows Server 2012 R2 federation server farm
3. Import the original configuration data into the Windows Server 2012 R2 AD FS farm
4. **Configure and customize the AD FS sign-in pages in the migrated AD FS farm**
5. **Other migration tasks**

Export and backup the AD FS configuration data

To export the AD FS configuration settings, perform the following procedures:

- To export service settings
- To export claims provider trusts and relying party trusts
- **To export relying party trusts**
- To back up custom attribute stores
- **To back up AD FS sign-in pages' settings and customizations**

To export service settings

1. Make sure that you have access to the following certificates and their private keys in a .pfx file:
   - The SSL certificate that is used by the federation server farm that you want to migrate
   - The service communication certificate (if it is different from the SSL certificate) that is used by the federation server farm that you want to migrate
   - All third-party party token-signing or token-encryption/decryption certificates that are used by the federation server farm that you want to migrate

   To find the SSL certificate, open the Internet Information Services (IIS) management console, Select **Default Web Site** in the left pane, click **Bindings…** in the **Action** pane, find and select the https binding, click **Edit**, and then click **View**.

   You must export the SSL certificate used by the federation service and its private key to a .pfx file. For more information, see Export the Private Key Portion of a Server Authentication Certificate.

   Note

If you plan to deploy the Device Registration Service as part of running your AD FS in Windows Server 2012 R2, you must obtain a new SSL cert. For more information, see Enroll an SSL Certificate for AD FS and Configure a federation server with Device Registration Service.

To view the token signing, token decryption and service communication certificates that are used, run the following Windows PowerShell command to create a list of all certificates in use in a file:

```
Get-ADFSCertificate | Out-File ".\certificates.txt"
```

2. Export AD FS federation service properties, such as the federation service name, federation service display name, and federation server identifier to a file.

   To export federation service properties, open Windows PowerShell and run the following command: `PSH:> Get-ADFSProperties | Out-File ".\properties.txt".`

   The output file will contain the following important configuration values:

Federation Service Property name as reported by Get-ADFSProperties	Federation Service Property name in AD FS management console
HostName	Federation Service name
Identifier	Federation Service identifier
DisplayName	Federation Service display name

3. Back up the application configuration file. Among other settings, this file contains the policy database connection string.

   To back up the application configuration file, you must manually copy the `%programfiles%\Active Directory Federation Services 2.0\Microsoft.IdentityServer.Servicehost.exe.config` file to a secure location on a backup server.

   Notes

   Make note of the database connection string in this file, located immediately after "policystore connectionstring="). If the connection string specifies a SQL Server database, the value is needed when restoring the original AD FS configuration on the federation server.

   The following is an example of a WID connection string: `"Data Source=\\.\pipe\mssql$microsoft##ssee\sql\query;Initial Catalog=AdfsConfiguration;Integrated Security=True"`. The following is an example of a SQL Server connection string: `"Data Source=databasehostname;Integrated Security=True"`.

4. Record the identity of the AD FS federation service account and the password of this account.

   To find the identity value, examine the **Log On As** column of **AD FS 2.0 Windows**

Service in the **Services** console and manually record this value.

Note

For a stand-alone federation service, the built-in NETWORK SERVICE account is used. In this case, you do not need to have a password.

5. Export the list of enabled AD FS endpoints to a file.

   To do this, open Windows PowerShell and run the following command: `PSH:> Get-ADFSEndpoint | Out-File ".\endpoints.txt".`

6. Export any custom claim descriptions to a file.

   To do this, open Windows PowerShell and run the following command: `Get-ADFSClaimDescription | Out-File ".\claimtypes.txt".`

7. If you have custom settings such as useRelayStateForIdpInitiatedSignOn configured in the web.config file, ensure you back up the web.config file for reference. You can copy the file from the directory that is mapped to the virtual path **"/adfs/ls"** in IIS. By default, it is in the **%systemdrive%\inetpub\adfs\ls** directory.

To export claims provider trusts and relying party trusts

1. To export AD FS claims provider trusts and relying party trusts, you must log in as Administrator (however, not as the Domain Administrator) onto your federation server and run the following Windows PowerShell script that is located in the **media/server_en-us/support/adfs** folder of the Windows Server 2012 R2 installation CD: `export-federationconfiguration.ps1`.

   Important

   The export script takes the following parameters:

   - Export-FederationConfiguration.ps1 -Path <string> [-ComputerName <string>] [-Credential <pscredential>] [-Force] [-CertificatePassword <securestring>]
   - Export-FederationConfiguration.ps1 -Path <string> [-ComputerName <string>] [-Credential <pscredential>] [-Force] [-CertificatePassword <securestring>] [-RelyingPartyTrustIdentifier <string[]>] [-ClaimsProviderTrustIdentifier <string[]>]
   - Export-FederationConfiguration.ps1 -Path <string> [-ComputerName <string>] [-Credential <pscredential>] [-Force] [-CertificatePassword <securestring>] [-RelyingPartyTrustName <string[]>] [-ClaimsProviderTrustName <string[]>]

     -RelyingPartyTrustIdentifier <string[]> - the cmdlet only exports relying party trusts whose identifiers are specified in the string array. The default is to export NONE of the relying party trusts. If none of RelyingPartyTrustIdentifier, ClaimsProviderTrustIdentifier, RelyingPartyTrustName, and ClaimsProviderTrustName is specified, the script will export all relying party trusts and claims provider trusts.

     -ClaimsProviderTrustIdentifier <string[]> - the cmdlet only exports claims provider trusts whose identifiers are specified in the string array. The default is to export NONE of the claims provider trusts.

-RelyingPartyTrustName <string[]> - the cmdlet only exports relying party trusts whose names are specified in the string array. The default is to export NONE of the relying party trusts.

-ClaimsProviderTrustName <string[]> - the cmdlet only exports claims provider trusts whose names are specified in the string array. The default is to export NONE of the claims provider trusts.

-Path <string> - the path to a folder that will contain the exported files.

-ComputerName <string> - specifies the STS server host name. The default is the local computer. If you are migrating AD FS 2.0 or AD FS in Windows Server 2012 to AD FS in Windows Server 2012 R2, this is the host name of the legacy AD FS server.

-Credential <PSCredential> - specifies a user account that has permission to perform this action. The default is the current user.

-Force – specifies to not prompt for user confirmation.

-CertificatePassword <SecureString> - specifies a password for exporting AD FS certificates' private keys. If not specified, the script will prompt for a password if an AD FS certificate with private key needs to be exported.

Inputs: None

Outputs: string - this cmdlet returns the export folder path. You can pipe the returned object to Import-FederationConfiguration.

To back up custom attribute stores

1. You must manually export all custom attribute stores that you want to keep in your new AD FS farm in Windows Server 2012 R2.

   Note
   In Windows Server 2012 R2, AD FS requires custom attribute stores that are based on .NET Framework 4.0 or above. Follow the instructions in Microsoft .NET Framework 4.5 to install and setup .Net Framework 4.5.

   You can find information about custom attribute stores in use by AD FS by running the following Windows PowerShell command: `PSH:>Get-ADFSAttributeStore`. The steps to upgrade or migrate custom attribute stores vary.
2. You must also manually export all .dll files of the custom attribute stores that you want to keep in your new AD FS farm in Windows Server 2012 R2. The steps to upgrade or migrate .dll files of custom attribute stores vary.

Create a Windows Server 2012 R2 federation server farm

1. Install the Windows Server 2012 R2 operating system on a computer that you want to function as a federation server and then add the AD FS server role. For more information, see Install the AD FS Role Service. Then configure your new federation service either through the Active Directory Federation Service Configuration Wizard or via Windows PowerShell. For more information, see “Configure the first federation server in a new federation server farm” in Configure a Federation Server.

   While completing this step, you must follow these instructions:

   - You must have Domain Administrator privileges in order to configure your federation service.
   - You must use the same federation service name (farm name) as was used in the AD FS 2.0 or AD FS in Windows Server 2012. If you do not use the same federation service name, the certificates that you backed up will not function in the Windows Server 2012 R2 federation service that you are trying to configure.
   - Specify whether this is a WID or SQL Server federation server farm. If it is a SQL farm, specify the SQL Server database location and instance name.
   - You must provide a pfx file containing the SSL server authentication certificate that you backed up as part of preparing for the AD FS migration process.
   - You must specify the same service account identity that was used in the AD FS 2.0 or AD FS in Windows Server 2012 farm.
2. Once the initial node is configured, you can add additional nodes to your new farm. For more information, see “Add a federation server to an existing federation server farm” in Configure a Federation Server.

Import the original configuration data into the Windows Server 2012 R2 AD FS farm

Now that you have an AD FS federation server farm running in Windows Server 2012 R2, you can import the original AD FS configuration data into it.

1. Import and configure other custom AD FS certificates, including externally enrolled token-signing and token- decryption/encryption certificates, and the service communication certificate if it is different from the SSL certificate.

   In the AD FS management console, select **Certificates**. Verify the service communications, token-encryption/decryption, and token-signing certificates by checking each against the values you exported into the certificates.txt file while preparing for the migration.

   To change the token-decrypting or token-signing certificates from the default self-signed certificates to external certificates, you must first disable the automatic certificate rollover feature that is enabled by default. To do this, you can use the following Windows PowerShell command:

```
Set-ADFSProperties –AutoCertificateRollover $false.
```

2. Configure any custom AD FS service settings such as AutoCertificateRollover or SSO lifetime using the Set-AdfsProperties cmdlet.
3. To import AD FS relying party trusts and claims provider trusts, you must be logged in as Administrator (however, not as the Domain Administrator) onto your federation server and run the following Windows PowerShell script that is located in the \support\adfs folder of the Windows Server 2012 R2 installation CD:

```
import-federationconfiguration.ps1
```

Important

The import script takes the following parameters:

- Import-FederationConfiguration.ps1 -Path <string> [-ComputerName <string>] [-Credential <pscredential>] [-Force] [-LogPath <string>] [-CertificatePassword <securestring>]
- Import-FederationConfiguration.ps1 -Path <string> [-ComputerName <string>] [-Credential <pscredential>] [-Force] [-LogPath <string>] [-CertificatePassword <securestring>] [-RelyingPartyTrustIdentifier <string[]>] [-ClaimsProviderTrustIdentifier <string[]>
- Import-FederationConfiguration.ps1 -Path <string> [-ComputerName <string>] [-Credential <pscredential>] [-Force] [-LogPath <string>] [-CertificatePassword <securestring>] [-RelyingPartyTrustName <string[]>] [-ClaimsProviderTrustName <string[]>]

  -RelyingPartyTrustIdentifier <string[]> - the cmdlet only imports relying party trusts whose identifiers are specified in the string array. The default is to import NONE of the relying party trusts. If none of RelyingPartyTrustIdentifier, ClaimsProviderTrustIdentifier, RelyingPartyTrustName, and ClaimsProviderTrustName is specified, the script will import all relying party trusts and claims provider trusts.

  -ClaimsProviderTrustIdentifier <string[]> - the cmdlet only imports claims provider trusts whose identifiers are specified in the string array. The default is to import NONE of the claims provider trusts.

  -RelyingPartyTrustName <string[]> - the cmdlet only imports relying party trusts whose names are specified in the string array. The default is to import NONE of the relying party trusts.

  -ClaimsProviderTrustName <string[]> - the cmdlet only imports claims provider trusts whose names are specified in the string array. The default is to import NONE of the claims provider trusts.

  -Path <string> - the path to a folder that contains the configuration files to be imported.

  -LogPath <string> - the path to a folder that will contain the import log file. A log file named “import.log” will be created in this folder.

  -ComputerName <string> - specifies host name of the STS server. The default

is the local computer. If you are migrating AD FS 2.0 or AD FS in Windows Server 2012 to AD FS in Windows Server 2012 R2, this parameter should be set to the hostname of the legacy AD FS server.

-Credential <PSCredential>- specifies a user account that has permission to perform this action. The default is the current user.

-Force – specifies to not prompt for user confirmation.

-CertificatePassword <SecureString> - specifies a password for importing AD FS certificates' private keys. If not specified, the script will prompt for a password if an AD FS certificate with private key needs to be imported.

Inputs: string - this command takes the import folder path as input. You can pipe Export-FederationConfiguration to this command.

Outputs: None.

Any trailing spaces in the WSFedEndpoint property of a relying party trust may cause the import script to error. In this case, manually remove the spaces from the file prior to import. For example, these entries cause errors:

```
<URI N="WSFedEndpoint">https://127.0.0.1:444 /</URI>
<URI N="WSFedEndpoint">https://myapp.cloudapp.net:83 /</URI>
```

They must be edited to:

```
<URI N="WSFedEndpoint">https://127.0.0.1:444/</URI>
<URI N="WSFedEndpoint">https://myapp.cloudapp.net:83/</URI>
```

Important

If you have any custom claim rules (rules other than the AD FS default rules) on the Active Directory claims provider trust in the source system, these will not be migrated by the scripts. This is because Windows Server 2012 R2 has new defaults. Any custom rules must be merged by adding them manually to the Active Directory claims provider trust in the new Windows Server 2012 R2 farm.

4. Configure all custom AD FS endpoint settings. In the AD FS Management console, select **Endpoints**. Check the enabled AD FS endpoints against the list of enabled AD FS endpoints that you exported to a file while preparing for the AD FS migration.

   - And -

   Configure any custom claim descriptions. In the AD FS Management console, select **Claim Descriptions**. Check the list of AD FS claim descriptions against the list of claim descriptions that you exported to a file while preparing for the AD FS migration. Add any custom claim descriptions included in your file but not included in the default list in AD FS. Note that Claim identifier in the management console maps to the ClaimType in the file.

5. Install and configure all backed up custom attribute stores. As an administrator, ensure any custom attribute store binaries are upgrade to .NET Framework 4.0 or higher before updating the AD FS configuration to point to them.

6. Configure service properties that map to the legacy web.config file parameters.
    - If **useRelayStateForIdpInitiatedSignOn** was added to the **web.config** file in your AD FS 2.0 or AD FS in Windows Sever 2012 farm, then you must configure the following service properties in your AD FS in Windows Server 2012 R2 farm:
        - AD FS in Windows Server 2012 R2 includes a **%systemroot%\ADFS\Microsoft.IdentityServer.Servicehost.exe.config** file. Create an element with the same syntax as the **web.config** file element: `<useRelayStateForIdpInitiatedSignOn enabled="true" />`. Include this element as part of **<microsoft.identityserver.web>** section of the **Microsoft.IdentityServer.Servicehost.exe.config** file.
    - If **<persistIdentityProviderInformation enabled="true|false" lifetimeInDays="90" enablewhrPersistence="true|false" />** was added to the **web.config** file in your AD FS 2.0 or AD FS in Windows Sever 2012 farm, then you must configure the following service properties in your AD FS in Windows Server 2012 R2 farm:

        i. In AD FS in Windows Server 2012 R2, run the following Windows PowerShell command: `Set-AdfsWebConfig -HRDCookieEnabled -HRDCookieLifetime`.
    - If **<singleSignOn enabled="true|false" />** was added to the **web.config** file in your AD FS 2.0 or AD FS in Windows Sever 2012 farm, you do not need to set any additional service properties in your AD FS in Windows Server 2012 R2 farm. Single sign-on is enabled by default in AD FS in Windows Server 2012 R2 farm.
    - If localAuthenticationTypes settings were added to the **web.config** file in your AD FS 2.0 or AD FS in Windows Sever 2012 farm, then you must configure the following service properties in your AD FS in Windows Server 2012 R2 farm:
        - Integrated, Forms, TlsClient, Basic Transform list into equivalent AD FS in Windows Server 2012 R2 has global authentication policy settings to support both federation service and proxy authentication types. These settings can be configured in the AD FS in Management snap-in under the **Authentication Policies**.

After you import the original configuration data, you can customize the AD FS sign in pages as needed. For more information, see Customizing the AD FS Sign-in Pages.

Migrating Active Directory Federation Services Role Service to Windows Server 2012 R2

Migrating the AD FS Federation Server Proxy

In Active Directory Federation Services (AD FS) in Windows Server 2012 R2, the role of a federation server proxy is handled by a new Remote Access role service called Web Application Proxy. In Windows Server 2012 R2, to enable your AD FS for accessibility from outside of the corporate network, you can deploy one or more Web Application Proxies. However, you cannot

migrate a federation server proxy running on Windows Server 2008 R2 or Windows Server 2012 to a Web Application Proxy running on Windows Server 2012 R2.

Important
The migration of a federation server proxy running on Windows Server 2008, Windows Server 2008 R2, or Windows Server 2012 to a Web Application Proxy running on Windows Server 2012 R2 is NOT supported.

If you want to configure AD FS in a Windows Server 2012 R2 migrated farm for extranet access, you must perform a fresh deployment of one or more Web Application Proxy computers as part of your AD FS infrastructure.

To plan Web Application Proxy deployment, you can review the information in the following topics:

- Step 1: Plan the Web Application Proxy Infrastructure
- Step 2: Plan the Web Application Proxy Server

To deploy Web Application proxy, you can follow the procedures in the following topics:

- Step 1: Configure the Web Application Proxy Infrastructure
- Step 2: Install and Configure the Web Application Proxy Server

Migrating Active Directory Federation Services Role Service to Windows Server 2012 R2

Verifying the AD FS Migration to Windows Server 2012 R2

Once you complete the same server migration of your Active Directory Federation Service (AD FS) farm to Windows Server 2012 R2, you can use the following procedure to verify that federation servers in your farm are operational; that is, that any client on the same network can reach your federation servers.

Membership in **Users**, **Backup Operators**, **Power Users**, **Administrators** or equivalent, on the local computer is the minimum required to complete this procedure. Review details about using the appropriate accounts and group memberships at Local and Domain Default Groups (http://go.microsoft.com/fwlink/?LinkId=83477).

To verify that a federation server is operational

1. Open a browser window and in the address bar, type the federation server name, and then append it with **federationmetadata/2007-06/federationmetadata.xml** to browse to the federation service metadata endpoint. For example, **https://fs.contoso.com/federationmetadata/2007-06/federationmetadata.xml** .

   If in your browser window you can see the federation server metadata without any SSL

errors or warnings, your federation server is operational.

2. You can also browse to the AD FS sign-in page (your federation service name appended with **adfs/ls/idpinitiatedsignon.htm**, for example, **https://fs.contoso.com/adfs/ls/idpinitiatedsignon.htm**). This displays the AD FS sign-in page where you can sign in with domain administrator credentials.

   Important
   Make sure to configure your browser settings to trust the federation server role by adding your federation service name (for example, **https://fs.contoso.com**) to the browser's local intranet zone.

Migrating Active Directory Federation Services Role Service to Windows Server 2012 R2

Migrate DHCP Server to Windows Server 2012 R2

DHCP server role migration involves moving the settings for your existing DHCP server to a new DHCP server on the network. The goal of this server migration is to install the DHCP server role on the Windows Server® 2012 R2 operating system so that it provides DHCP leases on a network without any perceptible change to DHCP client computers.

About this guide

This guide describes the steps for migrating existing DHCP server settings to a server that is running Windows Server 2012 R2. Migration documentation and tools ease the migration of server role settings and data from an existing server to a destination server that is running Windows Server 2012 R2. By using the tools that are described in this guide to migrate a DHCP server, you can simplify migration, reduce migration time, increase the accuracy of the migration process, and help eliminate possible conflicts that might otherwise occur during DHCP migration. For more information about the migration tools, see DHCP Server Migration: Appendix A.

Target audience

This guide is intended for information technology (IT) administrators, IT professionals, and other knowledge workers who are responsible for the operation and deployment of DHCP servers in a managed environment.

What this guide does not provide

The following scenarios are not supported or are beyond the scope of this guide.

- Clustering scenarios are not supported by this migration process. For more information about migrating DHCP Server in a cluster environment, see Migrating DHCP to a Cluster Running Windows Server 2008 R2 Step-by-Step Guide (http://go.microsoft.com/fwlink/?LinkId=140512) on the Windows Server TechCenter.

  Also see Migrate to DHCP Failover. DHCP failover is a new option for DHCP high availability, introduced in Windows Server 2012.
- Upgrading roles on the same computer is out of scope for this guide.
- Scenarios in which the new operating system is installed on existing server hardware by using the **Upgrade** option during setup (in-place upgrades) are not covered in this guide.
- Migrating more than one server role is not covered in this guide.

Supported migration scenarios

This guide gives you the instructions to migrate an existing DHCP server to a server that is running Windows Server 2012 R2. This guide does not contain instructions for migration when the source server is running multiple roles. If your server is running multiple roles, we recommend that you design a custom migration procedure specific to your server environment based on the information provided in other role migration guides. Migration guides for additional roles are available on the Windows Server 2012 TechCenter (http://technet.microsoft.com/library/jj134039.aspx).

Caution

If the source server is running multiple roles, some migration steps in this guide, such as those for computer name and IP configuration, can cause other roles that are running on the source server to fail.

This guide provides instructions only for migrating DHCP data and settings from a server that is being replaced by an x64-based server running Windows Server 2012 R2.

Supported operating systems

This guide provides instructions for migration of a DHCP server from a server that is running Windows Server 2003 or a later operating system to a server running Windows Server 2012 R2. Supported operating systems are listed in the following table.

Supported operating systems for migration

Source server processor	Source server operating system	Destination server operating system	Destination server processor
x86- or x64-based	Windows Server 2003 with Service Pack 2	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x86- or x64-based	Windows Server 2003 R2	Windows Server 2012 R2, both full and	x64-based

Source server processor	Source server operating system	Destination server operating system	Destination server processor
		Server Core installation options	
x86- or x64-based	Windows Server 2008	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x64-based	Windows Server 2008 R2	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x64-based	Server Core installation option of Windows Server 2008 R2	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x64-based	Windows Server 2012	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x64-based	Server Core installation option of Windows Server 2012	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x64-based	Windows Server 2012 R2	Windows Server 2012 R2, both full and Server Core installation options	x64-based
x64-based	Server Core installation option of Windows Server 2012 R2	Windows Server 2012 R2, both full and Server Core installation options	x64-based

The versions of operating systems shown in the previous table are the oldest combinations of operating systems and service packs that are supported. Newer service packs, if available, are supported for the migration of DHCP server settings.

Foundation, Standard, Enterprise, and Datacenter editions of Windows Server are supported as either source or destination servers.

Migrations between physical operating systems and virtual operating systems are supported.

Migration from a source server to a destination server that is running an operating system in a different system user interface (UI) language than the source server is not supported. The system UI language is the language of the localized installation package that was used to set up the Windows operating system. For example, you cannot use Windows Server migration tools to migrate roles, operating system settings, data, or shares from a computer that is running Windows Server 2008 R2 in the French system UI language to a computer that is running Windows Server 2012 R2 in the German system UI language.

Both x86-based and x64-based migrations are supported for Windows Server 2003 and Windows Server 2008. All editions of Windows Server 2012 R2 are x64-based.

Roles that are running on Server Core installations of Windows Server 2008 cannot be migrated, because there is no .NET Framework available on Server Core installations of Windows Server 2008.

We recommend migration rather than an upgrade even when the hardware is native x64-based. For example, with a server role split, a scenario in which the source server has more than one server role, because of increased use of this server you might decide to separate the roles onto several additional x64-based servers. In this case, migrating (not upgrading) individual server roles to other servers may be the best solution.

The server administrator can choose which components of an existing installation to migrate; together with the server role, these components usually include configuration, data, system identity, and operating system settings.

Supported role configurations

You can migrate all DHCP Server settings by using this guide, including registry and database settings.

Notes

If you are migrating a DHCP server in a cluster configuration, see Migrating DHCP to a Cluster Running Windows Server 2008 R2 Step-by-Step Guide (http://go.microsoft.com/fwlink/?LinkId=140512) on the Windows Server TechCenter.

Also see Migrate to DHCP Failover. DHCP failover is a new option for DHCP high availability, introduced in Windows Server 2012.

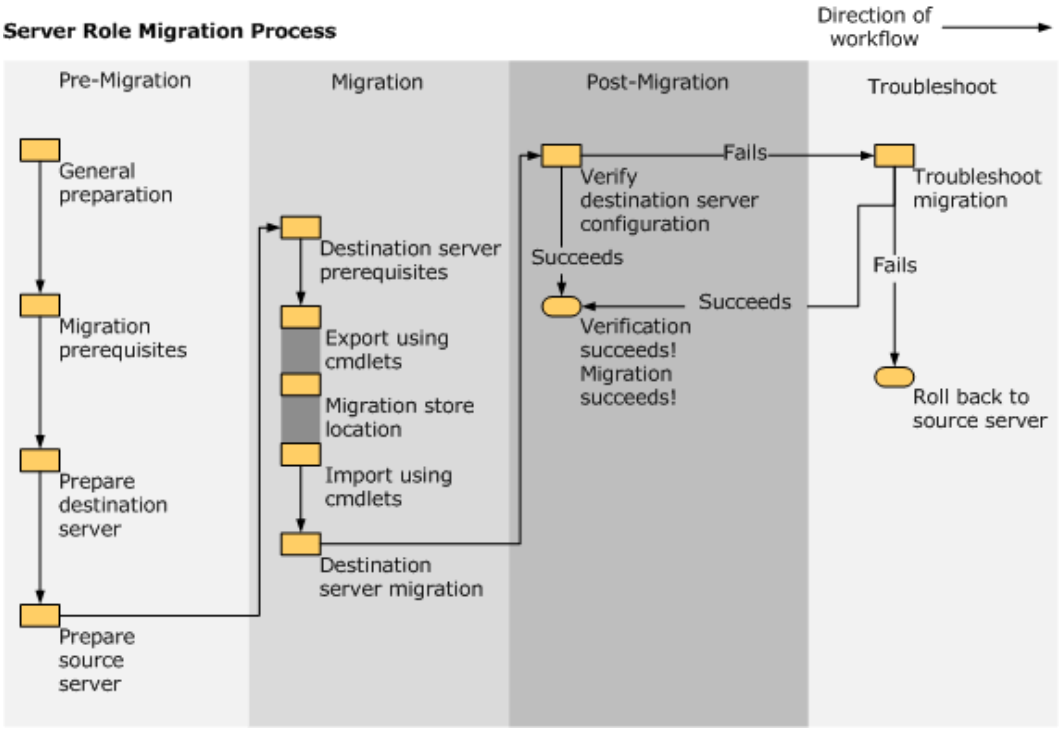
DHCP Server migration overview

DHCP Server migration is divided into the following major sections:

- DHCP Server Migration: Preparing to Migrate
- DHCP Server Migration: Migrating the DHCP Server Role
- DHCP Server Migration: Verifying the Migration
- DHCP Server Migration: Post-Migration Tasks

DHCP Server migration process

As shown in the following illustration, the pre-migration process involves the manual collection of data, followed by procedures on the destination and source servers. The migration process includes source and destination server procedures that use the **Export** and **Import** cmdlets to automatically collect, store, and then migrate server role settings. Post-migration procedures include verifying that the destination server successfully replaced the source server and then retiring or repurposing the source server. If the verification procedure indicates that the migration failed, troubleshooting begins. If troubleshooting fails, rollback instructions are provided to return to the use of the original source server.



Impact of migration on other computers in the enterprise

During migration, the source DHCP server might not be available. Therefore, client computers will not be able to obtain IP addresses from this DHCP server. We recommend that you maintain or create an auxiliary DHCP server so that client computers can obtain IP addresses while you migrate the primary DHCP server.

Be aware that if you choose to perform the migration without any auxiliary DHCP servers, all clients with valid leases must keep using those leases. If a lease for an existing client expires, that client will not be able to obtain an IP address. In addition, any new client that connects to the network will not be able to obtain an IP address when the single-source DHCP server is not available.

Permissions required to complete migration

The following permissions are required on the source server and the destination server:

- Domain administrative rights that are required to authorize DHCP Server.
- Local administrative rights are required to install or manage DHCP Server.
- Write permissions are required to the migration store location. For more information, see DHCP Server Migration: Preparing to Migrate.

Estimated duration

The migration can take two to three hours, including testing.

See also

DHCP Server Migration: Preparing to Migrate

DHCP Server Migration: Migrating the DHCP Server Role

DHCP Server Migration: Verifying the Migration

DHCP Server Migration: Post-Migration Tasks

DHCP Server Migration: Appendix A

DHCP Server Migration: Preparing to Migrate

Complete the following procedures before you migrate a DHCP Server from an x86-based or x64-based server to an x64-based server running Windows Server 2012 R2.

Migration planning

Install migration tools

Prepare the destination server

Prepare the source server

Migration planning

Membership in **Domain Administrators**, or equivalent, is the minimum required to complete these procedures. Review details about how to use the appropriate accounts and group memberships at Run a program with administrative credentials (http://go.microsoft.com/fwlink/?LinkId=131210).

To prepare for migration

- Identify your DHCP Server source and destination servers.
- Determine the domain, server name, and passwords on the source server. To identify the domain of the original server, click **Start**, right-click **Computer**, and then click

Properties.

- If you have not already done so, install Windows Server Migration Tools on the destination and source servers as instructed in Install migration tools.
- Before migration, install all critical updates and service packs on the source server that were released before Windows Server 2012 R2. It is a recommended best practice that all current critical updates and service packs are installed on both the source and the destination servers.
- Count the number of network adapters in the source and destination servers and make sure that they are equal in number. If the source server that is running DHCP Server has multiple network adapters and the DHCP Server service is bound to all and serving IP addresses on different subnets, the destination server that is running DHCP Server must also have multiple network adapters so that it can serve the same subnets as on the source server.
- Prepare a migration store file location. The store location must be accessible from the source server during the export and from the destination server during the import. Use a common drive that can contain all DHCP Server–related information from the source server. The storage location should be similar to the following: \\fileserver\users\username\.

Important

Before you run the **Import-SmigServerSetting**, **Export-SmigServerSetting**, or **Get-SmigServerFeature** cmdlets, verify that during migration, both source and destination servers can contact the domain controller that is associated with domain users or groups who are members of local groups on the source server.

Before you run the **Send-SmigServerData** or **Receive-SmigServerData** cmdlets, verify that during migration, both source and destination servers can contact the domain controller that is associated with those domain users who own files or shares that are being migrated.

Install migration tools

Install Windows Server Migration Tools on the destination and source servers. For more information, see Install, Use, and Remove Windows Server Migration Tools (http://technet.microsoft.com/library/jj134202.aspx).

Working with Windows PowerShell cmdlets

Cmdlets (pronounced *command-lets*) are built-in commands, installed by default when you install role services and features in Windows Server 2012 R2. Throughout this guide, there are several PowerShell cmdlets that you will have to run to carry out some of the migration steps. For more information about Windows PowerShell, see Windows PowerShell Support for Windows Server on the Microsoft Web site (http://technet.microsoft.com/en-us/library/hh801904.aspx).

Except where specifically noted, cmdlets are not case-sensitive.

You can obtain detailed Help about specific syntax, parameters, and usage guidelines for any installed cmdlet by typing **Get-Help** <cmdlet name> **-full** in a wps session, in which *cmdlet name* represents the name of the cmdlet for which you want help. Add the **-Verbose** parameter to a cmdlet to display detailed information about the operation in the Windows PowerShell session.

Although most commands for DHCP Server migration are cmdlets, you can run executable files in a session by adding an ampersand (&) before the executable file name. The ampersand is the call operator.

If the executable file is not in the current directory, add the fully qualified path, as shown in the following examples. If an executable file name contains spaces enclose the file name in quotation marks. If you are running the executable file from the current directory, precede the file name with **.**.

- Executable file that is not in the current directory: `PS C:\> & C:\Windows\System32\notepad.exe`
- Executable file that is in the current directory: `PS C:\Windows\System32> & .\notepad.exe`
- Executable file name that contains a space and is in the current directory: `PS C:\Windows\System32> & ".\executable test.exe"`

The commands in this document are provided in Windows PowerShell format. For more information, see DHCP Server Migration: Appendix A. You can run Command Prompt commands in a Windows PowerShell session by adding **cmd /C** before the command, as shown in the following example. The example shows the use of the **dir** command in wps.

```
cmd /C dir c:\*
```

Prepare the destination server

To install DHCP Server on the destination server, complete the menu-driven installation process. Complete the following procedure to prepare the destination server.

To prepare the destination server

1. Install Windows Server 2008 R2 and configure the destination server.
2. Make sure that there is sufficient disk space to store the DHCP Server database. The disk space needed varies with each installation and should be equal to or greater than the space for the DHCP Server database.
3. Add the destination server as a member server in the domain of the source server that is being replaced.
4. Verify that the destination server can resolve the names of domain users who are members of the local group during the import operation. If source and destination servers are in different domains, the destination server must be able to contact a global catalog server for the forest in which the source domain user accounts are located.
5. On a computer that is running Windows Server 2008 R2, open a wps session with elevated user rights. To do this, click **Start**, click **All Programs**, click **Accessories**, open the **Windows PowerShell** folder, right-click **Windows PowerShell**, and then click **Run as administrator**.

6. Load the Server Manager module into your wps session. To load the Server Manager module, type the following, and then press **Enter**.

```
Import-Module ServerManager
```

Note

It is not mandatory that DHCP Server is installed on the destination server before you import the settings. If the role is not installed on the destination server, it will be installed automatically during the import process. However, because installation of the role during import might extend downtime, we recommend that you install DHCP Server by using the Server Manager console on the destination server as part of your preparation for the migration.

7. On the destination server, run the following command to install DHCP Server:

```
Add-WindowsFeature DHCP
```

You can also install DHCP Server manually by using Server Manager. For more information, see Install Dynamic Host Configuration Protocol (DHCP) (http://go.microsoft.com/fwlink/?LinkId=128465).

Note

If you use the Add Roles Wizard in Server Manager to install DHCP Server on the destination server, you do not have to answer every question in the wizard. You can leave settings empty (the default) and then click **Next** through each wizard page. If you do not want to use the wizard, you can install DHCP Server by using the **Add-WindowsFeature** cmdlet, as described in this step.

8. By the end of the migration process, the destination server should have a static IP address. Although you will not change the destination server IP address now, consider the following scenarios in preparation for changing it when migration is complete.
   - If your migration scenario requires that you decommission and disconnect the source server from the network, only then can you make the IP address on the destination server the same as the IP address on the source server. The source server must be disconnected from the network or shut down so that there is no IP address conflict between the source server and destination server. However, the destination server can still serve clients that are searching for the legacy (source) server that was running DHCP Server.
   - If your migration scenario calls for continuing to run the source server on the network for other, non-DHCP purposes, you have to assign the destination server an unallocated IP address in the same subnet as the source server to avoid IP conflicts.
   - DHCP Server clients that attempt to renew an IP address lease send the renew request to the previous IP address of the DHCP server. If the source server has been decommissioned and then disconnected from the network and the new DHCP destination server is operating with a different IP address, this request initially fails because of the changed IP address. However, clients try to rediscover the IP address of the DHCP server on the network and therefore recover from this transient failure.

     Warning

If the source server is running multiple roles, renaming the source server or changing its IP address can cause other roles that are running on the source server to fail.

9. If the DHCP Server database path does not match the default path, you must ensure that the destination server has a disk with the same drive letter as seen in source server's DHCP Server database path. For more information, see the "Known issues" section of DHCP Server Migration: Appendix A.

The destination server is now prepared for migration.

Prepare the source server

Follow these steps to prepare the source server for migration.

To prepare the source server

1. Back up the source server. The backup should be a DHCP Server-specific backup, not a Windows backup. (A Windows backup backs up the complete operating system.) You can create the DHCP Server-specific backup by using the **Netsh** command-line tool or Microsoft Management Console (MMC).
   - In the DHCP MMC tree, right-click the server node to open DHCP backup options.
   - Create the backup by using the **Netsh** command-line tool. For more information, see Netsh Commands for Dynamic Host Configuration Protocol server (http://go.microsoft.com/fwlink/?LinkId=128496).

   Note
   The Windows Server 2003 operating system does not support **Netsh**-based backup.
2. If it is running, stop the DHCP Server service. In a session that was opened as described in step 5 of To prepare the destination server, type the following, and then press **Enter**.

   ```
   Stop-Service DHCPserver
   ```
3. If the DHCP Server database path does not match the default path, make sure that the destination server has a disk with the same drive letter as in source server's DHCP Server database path. For more information, see the "Known issues" section of DHCP Server Migration: Appendix A.

You are now ready to begin DHCP Server migration, as described in DHCP Server Migration: Migrating the DHCP Server Role.

See also

Migrate DHCP Server to Windows Server 2012 R2

DHCP Server Migration: Migrating the DHCP Server Role

DHCP Server Migration: Verifying the Migration

DHCP Server Migration: Post-Migration Tasks

DHCP Server Migration: Migrating the DHCP Server Role

Complete the following procedures to migrate a DHCP Server.

Migrating DHCP Server to the destination server

Migrating DHCP Server from the source server

Destination server final migration steps

Migrating DHCP Server to the destination server

Membership in **Domain Administrators** or equivalent is the minimum required to complete these procedures. Review details about how to use the appropriate accounts and group memberships at Run a program with administrative credentials (http://go.microsoft.com/fwlink/?LinkId=131210).

To migrate DHCP Server to the destination server

1. If it is not already installed, install DHCP Server on the destination server, as previously described in the “Prepare the destination server” section in DHCP Server Migration: Preparing to Migrate.
2. If it is running, stop the DHCP Server service by running the following command:

   ```
   Stop-Service DHCPserver
   ```

   If you are unsure whether the service is running, you can check its state by running the following command:

   ```
   Get-Service DHCPServer
   ```

Migrating DHCP Server from the source server

Follow these steps to migrate DHCP Server from the source server.

To migrate DHCP Server from the source server

1. Open a Windows PowerShell session with elevated user rights. To do this, click **Start**, click **All Programs**, click **Accessories**, open the **Windows PowerShell** folder, right-click **Windows PowerShell,** and then click **Run as administrator**.
2. Load Windows Server Migration Tools into your session.

   If you opened the current session by using the Windows Server Migration Tools shortcut on the **Start** menu, skip this step, and go to step 3. Only load the Windows Server Migration Tools snap-in in a session that was opened by using some other method, and into which the snap-in has not already been loaded. To load Windows Server Migration

Tools, type the following, and then press **Enter**.

```
Add-PSSnapin Microsoft.Windows.ServerManager.Migration
```

3. Collect data from the source server by running the **Export-SmigServerSetting** cmdlet as an administrator. The **Export-SmigServerSetting** cmdlet parameters can collect all source DHCP server data in a single file (Svrmig.mig). Or, the **Export-SmigServerSetting** cmdlet can be run multiple times, with each iteration using one or more parameters to collect and store data in multiple Svrmig.mig files. For more information, see DHCP Server Migration: Preparing to Migrate. Before you run this command, review the following:

   - When you run the command in step 4, you are prompted to provide a password to encrypt the migration store data. You must provide this same password to import from the migration store.
   - The **path** parameter can be an empty or nonempty directory. The actual data file in the directory (Svrmig.mig) is created by the **Export-SmigServerSetting** cmdlet. Therefore, the user does not have to specify a file name.
   - If the path is not a shared location that the destination server can read from, you must manually copy the migration store to the destination server or a location that the destination server can access.
   - If a migration store location already exists and you want to rerun the **Export-SmigServerSetting** cmdlet, you must move the Svrmig.mig file from that location and store it elsewhere, rename or first delete the migration store.
   - You can perform both IP and DHCP Server migration at the same time from a Windows PowerShell prompt by using the **Export-SmigServerSetting** cmdlet combined with the **IPConfig** switch, on a single command line.
   - Additional command line parameter information:
     - **-Users** and **-Group** parameters

     The **-Users** parameter must be specified only if the DHCP Administrators group includes local users. Otherwise, you can use the **-Group** parameter and all members of DHCP administrators will be migrated. Administrator group members can include domain users.

     Important
     If the source server is a domain controller, but the destination server is not, Domain Local groups are migrated as local groups, and domain users are migrated as local users.

     - The **-IPConfig** parameter collects IP information when it is used with the **Export-SmigServerSetting** cmdlet on the source server; the **-IPConfig** parameter applies settings when the **Import-SmigServerSetting** cmdlet is used on the destination server.

     If the source DHCP Server has multiple network adapters and the DHCP server service is bound to more than one network adapter and serving IP addresses on different subnets, the destination DHCP Server must also have multiple network

adapters so that it can serve the same subnets as the source DHCP Server. For more information, see Migrate IP Configuration to Windows Server 2012. Because IP configuration details will be used later when importing IP configuration settings to the destination server, it is a best practice to save the IP configuration settings by using the following command:

```
IPConfig /all > IPSettings.txt
```

The **Import-SmigServerSetting** cmdlet requires you to map the source physical address to the destination physical address.

Note

The destination server can be assigned the same static IP address as the source server, unless other roles on the source server must continue to run on it. In that case, the static IP address of the destination server can be any unallocated static IP address in the same subnet as the source server.

4. On the source server, run the **Export-SmigServerSetting** cmdlet, where <*storepath*> is the path that will contain the Svrmig.mig file after this step is completed. An example of the path is \\fileserver\users\username\dhcpstore.

   ```
   Export-SmigServerSetting -featureID DHCP -User All -Group -
   IPConfig -path <storepath> -Verbose
   ```

   For more information about how to export IP configuration settings, see Migrate IP Configuration to Windows Server 2012.

5. On the source server, delete the DHCP authorization for the source DHCP server by running the following command, where *Server FQDN* is the fully qualified domain name (FQDN) of the DHCP server and *Server IPAddress* is the IP address of the server. The command parameters are case-sensitive and must appear exactly as shown.

   ```
   Netsh DHCP delete server <Server FQDN> <Server IPAddress>
   ```

Destination server final migration steps

Return to the destination server and follow these steps to complete the migration.

1. Before you use the **Import-SmigServerSetting** cmdlet to import the DHCP server settings, be aware of the following conditions:
   - You can either use a single command line with all the parameters to import DHCP settings (as when you export data from the source server) or you can use the **Import** cmdlet multiple times to import data one parameter at a time.
   - If you decide to run the **Import-SmigServerSetting** cmdlet separately to import the IP settings, see Migrate IP Configuration to Windows Server 2012. Use the source IPSettings.txt file, referred to in step 3 of the previous procedure. You will map the source physical addresses to the destination physical addresses in step 3 of this procedure.

     Important

If you will be importing role and IP settings separately, you should import IP settings first to avoid any IP conflicts. You can then import the DHCP role.

- If the DHCP Administrators group includes local users, then use the **-Users** parameter combined with the **-Group** parameter to import local users into the DHCP Administrators group. If it only contains domain users, then use only the **-Group** parameter.

  Security

  If the source server is a domain member server, but the destination server is a domain controller, imported local users are elevated to domain users, and imported local groups become Domain Local groups on the destination server.

- If the DHCP Server role that you are migrating has not yet been installed on the destination server, the **Import-SmigServerSetting** cmdlet will install that DHCP Server role and its dependencies, described in the next step. you might have to restart the destination computer to complete the installation after the DHCP Server role is installed by the cmdlet. Then, to complete the import operation after you restart the computer you must run the **Import-SmigServerSetting** cmdlet again along with the **-Force** parameter..

2. On the destination server, run the following command, where *<storepath>* is the available path that contains the Svrmig.mig file, *<SourcePhysicalAddress-1>* and *<SourcePhysicalAddress-2>* are comma-separated lists of the physical addresses of the source network adapter, and *<TargetPhysicalAddress-1>* and *<TargetPhysicalAddress-2>* are comma-separated lists of the physical addresses of the destination network adapter:

   ```
   Import-SmigServerSetting -featureid DHCP -User All -Group -
   IPConfig <All | Global | NIC>
   -SourcePhysicalAddress <SourcePhysicalAddress-
   1>,<SourcePhysicalAddress-2>
   -TargetPhysicalAddress <TargetPhysicalAddress-
   1>,<TargetPhysicalAddress-2>
   -Force -path <storepath> -Verbose
   ```

   The **-IPConfig** switch should be used with the value **All** in case the user wants to import all source settings. For more information, see Migrate IP Configuration to Windows Server 2012.

   Important

   If you import the source server IP address to the target server together with the DHCP role without disconnecting or changing the IP address of the source server, an IP address conflict will occur.

3. Run the following command to start the DHCP service:

   ```
   Start-Service DHCPServer
   ```

4. Authorize the destination server. Command parameters are case-sensitive and must appear exactly as shown. On the destination server, run the following command where *Server FQDN* is the FQDN of the DHCP Server and *Server IPAddress* is the IP address of the server:

   ```
   netsh DHCP add server <Server FQDN> <Server IPAddress>
   ```

Note

After authorization, the Server Manager event log might show event ID 1046. This is a known issue and is expected to occur only once. The event can be safely ignored.

When this migration is finished, client computers on the network server are served by the new x64-based destination server running Windows Server 2012 R2. The migration is complete when the destination server is ready to serve IP addresses to the network.

DHCP Server Migration: Preparing to Migrate

DHCP Server Migration: Verifying the Migration

DHCP Server Migration: Post-Migration Tasks

DHCP Server Migration: Appendix A

DHCP Server Migration: Verifying the Migration

When all the migration steps are complete, you can use the following procedure to verify that the DHCP server role migration was successful. If the migration failed, you can return to the previous valid configuration by following the steps in DHCP Server Migration: Post-Migration Tasks.

Verifying destination server configuration

Follow these steps to confirm that the DHCP destination server is now serving the domain.

Membership in **Domain Administrators**, or equivalent, is the minimum required to complete this procedure. Review details about how to use the appropriate accounts and group memberships at Understanding Groups: Default groups (http://go.microsoft.com/fwlink/?LinkId=83477).

To verify the configuration of the destination server

1. Make sure that the destination server is authorized by running the following command in a Windows PowerShell window:

   ```
   netsh DHCP show server
   ```

   The output of this command must contain the name of the DHCP destination server.
2. Check whether DHCP server is running on the destination server. In Task Manager, on the **Services** tab, the DHCP server status should be **Started**. You also use Task Manager to confirm that the status of the source server is **Stopped**.
3. Verify that the client computers are correctly receiving IP addresses on request by

running the following commands at a command prompt on a client computer:

```
ipconfig /release
ipconfig /renew
```

If the IP address of the DHCP server has not changed, you do not have to run the **ipconfig /release** command. Running **ipconfig /renew** should be sufficient.

The output of these commands should show that the client computer was issued an IP address.

4. Use the DHCP console to verify that the scopes and other settings were migrated. To connect to the destination server, click **Action**, click **Add Server**, and then type the IP address or host name of the DHCP server. In the console tree, expand the server node, and then expand the IPv4 and IPv6 nodes to confirm that the scopes have been migrated. Then locate the folders for the scopes and view the address range, reservations, scope options, and active leases to verify the same. You can also go to the Server Options folder and verify the migrated server options.

DHCP Server Migration: Preparing to Migrate

DHCP Server Migration: Migrating the DHCP Server Role

DHCP Server Migration: Post-Migration Tasks

DHCP Server Migration: Appendix A

DHCP Server Migration: Post-Migration Tasks

The post-migration tasks for the source server are optional, depending on your migration scenario.

Completing migration

Restoring DHCP in the event of migration failure

Troubleshooting cmdlet-based migration

Completing migration

Migration is complete after you have verified that the destination server, not the source server, is now serving the network. If your verification efforts demonstrate that the migration failed, see “Restoring DHCP in the event of migration failure” later in this topic.

Retiring DHCP on your source server

After you have verified the migration, you can disconnect, repurpose, or retire the source server. If the source server is running other server roles, it should be left on the network. If you do not have to use this computer, you can store it as a backup in case you ever have to revert to your previous DHCP configuration.

- If your migration scenario includes a standalone DHCP Server, then this source server was taken offline after the export file was created, as described in DHCP Server Migration: Preparing to Migrate. In this scenario, the DHCP service was interrupted from the time that it was stopped until the migration was complete on the new server, as described in DHCP Server Migration: Migrating the DHCP Server Role.
- If your migration scenario includes more than one DHCP Server in a domain, a backup or other DHCP server continues to serve IP addresses during the migration so that services to clients are never interrupted. The migration is complete on the new server when the IP address of the source server is migrated to the destination server.

Retiring your source server

After you have confirmed that the destination server is performing the functions previously handled by the source server, you can retire or repurpose the source server, depending on your needs. Follow your organization's policy regarding server decommissioning. For information about decommissioning a domain controller, see Decommissioning a Domain Controller (http://go.microsoft.com/fwlink/?LinkID=128290).

Warning
After the source server is repurposed as a member server, otherwise repurposed or retired from service, you cannot roll that server back to its previous working state.

Restoring DHCP in the event of migration failure

If the migration of DHCP Server fails, you have these options:

- If the source server has not been repurposed, an administrator can reassign the IP configuration settings, reauthorize the server, and restart the DHCP service on the original server.
- Use the backup files that were created on the source server, as described in DHCP Server Migration: Preparing to Migrate, to restore DHCP server on the original DHCP server.

Estimated time to complete a rollback

You should be able to complete a rollback in one to two hours.

Troubleshooting cmdlet-based migration

The Windows Server Migration Tools deployment log file is located at %*windir*%\Logs\SmigDeploy.log. Additional Windows Server Migration Tools log files are created at the following locations.

- %*windir*%\Logs\ServerMigration.log
- On Windows Server 2008 and Windows Server 2008 R2: %*localappdata*%\SvrMig\Log
- On Windows Server 2003: %*userprofile*%\Local Settings\Application Data\SvrMig\Log

If migration log files cannot be created in the previous locations, **ServerMigration.log** and **SmigDeploy.log** are created in %*temp*%, and other logs are created in %*windir*%\System32.

For DHCP-specific troubleshooting tips, see Troubleshooting DHCP servers on the Windows Server TechCenter (http://go.microsoft.com/fwlink/?LinkId=128533). Although these tips are written for Windows Server 2003, they also address common issues that apply to later versions of the operating system.

If a migration cmdlet fails, and the wps session closes unexpectedly with an access violation error message, look for a message similar to the following example in the %*localappdata*%\SvrMig\Logs\setuperr.log file.FatalError [0x090001] PANTHR Exception (code 0xC0000005: ACCESS_VIOLATION) occurred at 0x000007FEEDE9E050 in C:\Windows\system32\migwiz\unbcl.dll (+000000000008E050). Minidump attached (317793 bytes).

This failure occurs when the server cannot contact domain controllers that are associated with domain users or groups who are members of local groups, or who have rights to files or shares that are being migrated. When this happens, each domain user or group is displayed in the GUI as an unresolved security identifier (SID). An example of a SID is **S-1-5-21-1579938362-1064596589-3161144252-1006**.

To prevent this problem, verify that required domain controllers or global catalog servers are running, and that network connectivity allows communication between both source and destination servers and required domain controllers or global catalog servers. Then, run the cmdlets again.

If connections between either the source or destination servers and the domain controllers or global catalog servers cannot be restored, do the following.

1. Before you run **Export-SmigServerSetting**, **Import-SmigServerSetting** or **Get-SmigServerFeature** again, remove all unresolved domain users or groups who are members of local groups from the server on which you are running the cmdlet.
2. Before you run **Send-SmigServerData** or **Receive-SmigServerData** again, remove all unresolved domain users or groups who have user rights to files, folders, or shares on the migration source server.

Viewing the content of Windows Server Migration Tools result objects

All Windows Server Migration Tools cmdlets return results as objects. You can save result objects, and query them for more information about settings and data that were migrated. You can also use result objects as input for other wps commands and scripts.

Result object descriptions

The Windows Server Migration Tools **Import-SmigServerSetting** and **Export-SmigServerSetting** cmdlets return results in a list of **MigrationResult** objects. Each **MigrationResult** object contains information about the data or setting that the cmdlet processes, the result of the operation, and any related error or warning messages. The following table describes the properties of a **MigrationResult** object.

Property name	Type	Definition
ItemType	Enum	The type of item being migrated. Values include **General**, **WindowsFeatureInstallation**, **WindowsFeature**, and **OSSetting**.
ID	String	The ID of the migrated item. Examples of values include **Local User**, **Local Group**, and **DHCP**.
Success	Boolean	The value **True** is displayed if migration was successful; otherwise, **False** is displayed.
DetailsList	List <MigrationResultDetails>	A list of **MigrationResultDetails** objects.

Send-SmigServerData and **Receive-SmigServerData** cmdlets return results in a list of **MigrationDataResult** objects. Each **MigrationDataResult** object contains information about the data or share that the cmdlet processes, the result of the operation, any error or warning messages, and other related information. The following table describes the properties of a **MigrationDataResult** object.

Property name	Type	Definition
ItemType	Enum	The type of migrated item. Values include **File**, **Folder**, **Share**, and **Encrypted File**.
SourceLocation	String	The source location of the item,

Property name	Type	Definition
		shown as a path.
DestinationLocation	String	The destination location of the item, shown as a path.
Success	Boolean	The value **True** is displayed if migration was successful; otherwise, **False** is displayed.
Size	Integer	The item size, in bytes.
ErrorDetails	List <MigrationResultDetails>	A list of **MigrationResultDetails** objects.
Error	Enum	Errors enumeration for errors that occurred.
WarningMessageList	List <String>	A list of warning messages.

The following table describes the properties of objects within the **MigrationResultDetails** object that are common to both **MigrationResult** and **MigrationDataResult** objects.

Property name	Type	Definition
FeatureId	String	The name of the migration setting that is related to the item. Examples of values include **IPConfig** and **DNS**. This property is empty for data migration.
Messages	List <String>	A list of detailed event messages.
DetailCode	Integer	The error or warning code associated with each event message.
Severity	Enum	The severity of an event, if events occurred. Examples of values include **Information**, **Error**, and **Warning**.
Title	String	Title of the result object. Examples of values include the network adapter physical

Property name	Type	Definition
		address for IP configuration, or user name for local user migration.

Examples

The following examples show how to store the list of the result objects in a variable, and then use the variable in a query to return the content of result objects after migration is complete.

To store a list of result objects as a variable for queries

1. To run a cmdlet and save the result in variable, type a command in the following format, and then press **Enter**.

   ```
   $VariableName = $(Cmdlet)
   ```

   The following is an example.

   ```
   $ImportResult = $(Import-SmigServerSetting -FeatureId DHCP -
   User all -Group -Path D:\rmt\DemoStore -force -Verbose)
   ```

   This command runs the **Import-SmigServerSetting** cmdlet with several parameters specified, and then saves result objects in the variable **ImportResult**.

2. After the **Import-SmigServerSetting** cmdlet has completed its operations, return the information that is contained in the result object by typing a command in the following format, and then pressing **Enter**.

   ```
   $VariableName
   ```

   In the following example, the variable is named **ImportResult**.

   ```
   $ImportResult
   ```

   This command returns information that was contained in the result objects that were returned by **Import-SmigServerSetting** in the example shown in step 1. The following is an example of the output that is displayed by calling the **ImportResult** variable.

   ```
               ItemType  ID                                Success
   DetailsList
               --------  --                                -------
   -----------
             OSSetting  Local User                          True
   {Local User, Loc...
             OSSetting  Local Group                         True
   {Local Group, Lo...
        WindowsFeature  DHCP                                True
   {}
   ```

Each line of the previous sample is a migration result for an item that was migrated by using the **Import-SmigServerSetting** cmdlet. The column heading names are properties of **MigrationResult** objects. You can incorporate these properties into another command to return more detail about result objects, as shown by examples in step 3 and forward.

3. To display a specific property for all result objects in the list, type a command in the following format, and then press **Enter**.

   ```
   $<VariableName>| Select-Object -ExpandProperty <PropertyName>
   ```

   The following is an example.

   ```
   $importResult | Select-Object -ExpandProperty DetailsList
   ```

4. You can run more advanced queries to analyze result objects by using wps cmdlets. The following are examples.

   - The following command returns only those details of result objects that use the ID **Local User**.

     ```
     $ImportResult | Where-Object { $_.ID -eq "Local User" } |
     Select-Object -ExpandProperty DetailsList
     ```

   - The following command returns only those details of result objects that use an ID of **Local User** that have a message severity equal to **Warning**.

     ```
     $ImportResult | Where-Object { $_.ID -eq "Local User" } |
     Select-Object -ExpandProperty DetailsList | ForEach-Object {
     if ($_.Severity -eq "Warning") {$_} }
     ```

   - The following command returns only the details of result objects that use an ID of **Local Group** that also have the title **Remote Desktop Users**.

     ```
     $ImportResult | Where-Object { $_.ID -eq "Local Group" } |
     Select-Object -ExpandProperty DetailsList | ForEach-Object {
     if ($_.Title -eq "Remote DesktopUsers") {$_} }
     ```

More information about querying results

For more information about the cmdlets that are used in the previous examples, see the following additional resources.

- Where-Object on the Microsoft Script Center Web site (http://go.microsoft.com/fwlink/?LinkId=134853).
- Select-Object on the Microsoft Script Center Web site (http://go.microsoft.com/fwlink/?LinkId=134858).
- ForEach-Object on the Microsoft Script Center Web site (http://www.microsoft.com/technet/scriptcenter/topics/msh/cmdlets/foreach-object.mspx)

Migration tools

Migration tools are provided in Windows Server® 2012 R2. The tools for earlier versions of the Windows operating system are also available in Windows Server 2012 R2.

Follow these steps to access the tools on the destination server:

1. Open Server Manager.
2. Click **Action**, and then select **Add Features**. The Add Features Wizard opens.
3. On the **Select Features** page, from the **Features** list, select **Windows Server Migration Tools**, and then click **Next**.
4. Complete the steps in the wizard, and then click **Close**.

The previous steps do not work for Server Core installations. To install the migration tools on a Server Core installation, see the Install Windows Server Migration Tools topic in Install, Use, and Remove Windows Server Migration Tools.

Installing and using Windows PowerShell with migration cmdlets

To access, download, and install migration tools (the migration toolkit), any role-specific tools, and Windows PowerShell, see Install, Use, and Remove Windows Server Migration Tools.

Known issues

If the DHCP installation on the source server has a database path that varies from the default, before you perform the import, provide the destination server with a volume with the same drive letter on which the DHCP server database exists on the source server. For example, if the DHCP server database on the source server is located on D:\, then the destination server should have a volume with the driver letter D.

If you cannot match the volume on the destination server that has the same driver letter as that shown for the source DHCP server database, then the DHCP database path on the source server must be changed back to the default path (%systemroot%\system32\dhcp) before you start the migration.

Migrate Hyper-V to Windows Server 2012 R2 from Windows Server 2012

With Hyper-V, you can create a virtualized server computing environment by using a technology that is part of Windows. This guide provides information and instructions about migrating the Hyper-V role that include virtual machines, data, and operating system settings from the source server running Hyper-V in Windows Server 2012 to the destination server that is running the Windows Server 2012 R2 operating system.

About this guide

This guide describes how to migrate the Hyper-V role by providing preparation, migration, and verification steps.

Migration documentation and tools facilitate the migration of server role settings and data from an existing source server to a destination server that is running Windows Server 2012 R2. By using the tools that are described in this guide, you can simplify the migration process, reduce migration time, increase the accuracy of the migration process, and help eliminate possible conflicts that might otherwise occur during the migration process.

In addition to the migration options that are described in this topic, Virtual Machine Manager in Microsoft System Center 2012 R2 can facilitate and automate a considerable part of the migration process. For more information about Virtual Machine Manager, see Virtual Machine Manager.

Target audience

This document is intended for information technology (IT) professionals who are responsible for operating and deploying Hyper-V in a managed environment.

What this guide does not provide

- Migration of Hyper-V from one server that runs Windows Server 2008 R2 to another server that runs Windows Server 2012 R2.
- Instructions for migrating more than one server role at one time.

- Migration of Hyper-V from one server that runs Windows Server 2012 R2 to another server that runs Windows Server 2012 R2. Instead, this process is supported by Hyper-V management tools and features. The general process is as follows:
    a. Determine whether to use export and import or live migration to move the virtual machines:
        - Export and import can be used in either a workgroup or a domain environment. In Hyper-V running on Windows Server 2012 R2, you can now export a running virtual machine.
        - Live migration requires a domain environment and some additional configuration, but the virtual machine is running throughout the move process.
    b. Add the Hyper-V role to the destination server. You can configure the default storage locations and live migration when you add the role.
    c. Configure virtual switches, and optionally, other networking features on the destination server. Management tools include the Windows PowerShell cmdlets New-VMSwitch and Set-VMSwitch, and the Hyper-V Virtual Switch Manager in the Hyper-V Manager Console.
    d. Move the virtual machines by using export and import or live migration. Management tools include the Windows PowerShell cmdlets Export-VM, Import-VM, and Move-VM and the **Export**, **Import**, and **Move** menu commands in the Hyper-V Manager Console.

Supported migration scenarios

This guide provides you with instructions to migrate a server that is running Hyper-V in Windows Server 2012 to a server that is running Windows Server 2012 R2. This guide does not contain instructions for migration when the source server is running multiple roles. If your server is running multiple roles, we recommend that you design a custom migration procedure that is specific to your server environment and is based on the information in other role migration guides. Migration guides for additional roles are available on the Windows Server Migration Portal.

Migration dependencies

The Hyper-V role does not depend on any other roles. As a best practice, we recommend that no other roles are installed on a server running Hyper-V.

Migration scenarios that are not supported

The following migration scenarios are not supported:

- Virtual machine configuration under one of the following conditions:
    - When the number of virtual processors that are configured for the virtual machine is greater than the number of logical processors on the destination server.
    - When the memory that is configured for a virtual machine is greater than the available memory on the destination server.

Overview of migration process for this role

Hyper-V role migration involves moving the virtual machines, virtual networks, and all the associated settings from one physical computer to another physical computer in the enterprise. The process supports moving from a server running Hyper-V in Windows Server 2012 to a server running Hyper-V in Windows Server 2012 R2. The Hyper-V role does not depend on any other roles.

The migration tools include Windows PowerShell cmdlets that you can use to perform some of the tasks that are required to migrate the Hyper-V role and script or to automate the migration process.

In previous versions of Hyper-V, you were required to shut down a virtual machine before you moved it to a new server. If the move was performed correctly, downtime was limited, but still, there was downtime. A new feature in Windows Server 2012 R2, cross-version live migration, supports moving a running virtual machine from Windows Server 2012 to Windows Server 2012 R2. The Windows PowerShell Export-VM cmdlet captures the majority of the Hyper-V settings that are required to perform a successful migration, which includes the virtual machine configurations, virtual networks, and virtual hard disks. Now you can decide how to move virtual machines to Windows Server 2012 R2, where in the past, your options where limited.

The following options are available to move a virtual machine:

- In-place upgrade
- Cross-version live migration
- Export and Import
- Copy Cluster Role Wizard

For additional information about each option, see Hyper-V: Migration Options.

This guide explains the migration process for the following three main scenarios:

- Hyper-V: Stand-alone Migration
- Hyper-V Cluster Using Separate Scale-Out File Server Migration
- Hyper-V Cluster Using Cluster Shared Volumes (CSV) Migration

Estimated duration

The length of time it takes to migrate the Hyper-V role depends on the size of the data to be transferred and on the tools that are used. Of the various types of files to be transferred, the virtual hard disk (VHD), .vhd and .vhdx files, have the largest file sizes from a few gigabytes to many gigabytes in size. The length of time that is required for migration is largely affected by the size of the VHD files and by the network bandwidth.

Additional references

Windows Server Migration forum

Hyper-V: Migration Options

When you migrate virtual machines from the Windows Server 2012 operating system to the Windows Server 2012 R2 operating system, you have various options on how to migrate your virtual machines. You now can select the migration options that meet the requirements of your environment.

Hyper-V migration options

Depending on your requirements and service level agreements that must be maintained, you can use one migration option or a combination of migration options. For example, if you have virtual machines that either must be running all the time or that only have a short maintenance period for you to shut them down, you might select to use cross-version live migration to move the virtual machines from Windows Server 2012 to Windows Server 2012 R2. For other virtual machines that are not as critical, have a long maintenance period, or might take too long to move by using live migration, you can use the Copy Cluster Roles Wizard or **Export / Import**, which depends on your environment.

The following table shows the benefits and disadvantages of the various migration options.

Migration option	Benefits	Disadvantages
In-place upgrade	• No new hardware required.	• Virtual machines must be shut off during the upgrade.
Cross-version live migration	• Virtual machines continue running during migration. • If the virtual hard disk is stored on a Scale-out File Server share that is accessible from both servers, the virtual hard disks do not have to be copied. • Moves virtual machines from one Hyper-V cluster to another cluster without any downtime. • Migrates individual virtual machines that are part of the Hyper-V cluster.	• Requires additional hardware or extra capacity in the existing cluster to create the destination cluster. • The amount of time it takes to migrate a virtual machine depends on various factors, for example, the size of memory that is configured for the virtual machine and the network configuration. If the virtual hard disks are not stored on a Scale-out File Server, additional time is required to move the virtual hard disk. • The virtual machine must be removed from the existing cluster before it is

Migration option	Benefits	Disadvantages
		moved to the new cluster. After the virtual machine has successfully moved to new cluster node, high availability is added to the virtual machine. During the move process, the virtual machine is not protected by the cluster services.
Copy Cluster Roles Wizard	• Easily migrates a Hyper-V cluster from Windows Server 2012 to Windows Server 2012 R2. • Tests the Copy Cluster Roles process without affecting production. • Reverses the process if you encounter any issues. • Copies roles on test clusters to production clusters.	• All virtual machines on the same Shared Clustered Volume are migrated at the same time. • Virtual machines must be shut down for a short period of time. • The Copy Cluster Wizard does not copy the Hyper-V replication settings when it copies a virtual machine to a new failover cluster. Hyper-V replication must be re-enabled on the virtual machine after it is copied. For the **Initial Replication Method**, select **Use an existing virtual machine on the Replica server as the initial copy**. • Requires additional hardware.
Export / Import	• Migrates one virtual machine at a time. • Controls the method of copying the virtual machine to the new server.	• The virtual machine is shut down during the Export / Import process. • Requires additional hardware. • The Import of a virtual machine removes any Hyper-V Replica configuration settings for a virtual machine. Hyper-V

Migration option	Benefits	Disadvantages
		replication must be re-enabled on the virtual machine after it is imported. For the **Initial Replication Method**, select **Use an existing virtual machine on the Replica server as the initial copy**.

The following table shows the available options to use in different deployments of Hyper-V.

Scenario / Migration option	In-place upgrade	Export / Import	Cross-version live migration	Copy Cluster Roles Wizard
Standalone host	Yes	Yes	Yes	No
Hyper-V Cluster with Cluster Shared Volumes (CSV)	No	Yes	Yes, the virtual machine must be removed from the cluster first, and the virtual hard disks must be copied as part of the live migration.	Yes
Hyper-V Cluster with a separate Scale-out File Server for storage	No	Yes	Yes, the virtual machine must be removed from the cluster first.	Yes

Important
When Hyper-V Replica is enabled, we recommend that you migrate the virtual machines on the Replica site first, and then migrate the primary site.

Cross-version live migration

The upgrade to a new version of Windows Server no longer requires downtime of the virtual machines. In Windows Server 2012 R2, Hyper-V live migration has been updated to support the migration of virtual machines in Windows Server 2012 to Windows Server 2012 R2. If the virtual hard disk files are stored on an SMB 3.0 share that is accessible from both the source and destination server, you only must move the virtual machine configuration and memory files, but not the virtual hard disk files. If the virtual hard disk files are not stored on an SMB 3.0 share, or if the share is not accessible to the destination server, you can use the Shared Nothing Live

Migration to migrate the virtual hard disk files, virtual machine configuration files, and the running virtual machine with no downtime.

Hyper-V Replica

Hyper-V Replica was introduced in Windows Server 2012 and provides asynchronous replication of Hyper-V virtual machines between two hosting servers. It is simple to configure and does not require either shared storage or any particular storage hardware. Any server workload that can be virtualized in Hyper-V can be replicated. Replication works over any ordinary IP-based network, and the replicated data can be encrypted during transmission. Hyper-V Replica works with standalone servers, failover clusters, or a mixture of both. The servers can be physically co-located or widely separated geographically. The physical servers do not have to be in the same domain or even be joined to any domain at all.

Consider the following factors for the move from Windows Server 2012 to Windows Server 2012 R2 when you use Hyper-V Replica:

- You must upgrade the Replica server first. A Windows Server 2012 R2 Replica server can accept replication from a primary server that runs Windows Server 2012. However, a Windows Server 2012 Replica server cannot accept replication from a primary server that runs Windows Server 2012 R2.
- When you upgrade the Replica server, consider the following factors:
  - When you perform an in-place upgrade on the Replica server, the post-upgrade of the Replica server to Windows Server 2012 R2 replication continues from the primary server that runs Windows Server 2012 at the default replication frequency of 5 minutes.
  - When you move the virtual machines to a new server that runs Windows Server 2012 R2, you must update the virtual machine replication settings on the primary server with the name of the new Replica server or Hyper-V Replica Broker. Until the Replica server name is updated, replication does not resume.
  - You can start to use new Hyper-V Replica features, such as extended replication from the Replica server.
  - You can add new virtual machines to the primary server that runs Windows Server 2012 and start replication to a Replica server that runs Windows Server 2012 R2.
  - In case of emergency, you can fail over your virtual machines from the primary server to the Replica server. You cannot start reverse replication because replication is not supported from Windows Server 2012 R2 to Windows Server 2012.

    Note

    At this point, the virtual machine is no longer protected by Hyper-V Replica. You can configure extended replication by using another server running Hyper-V in Windows Server 2012 R2. After the primary server has been upgraded to Windows Server 2012 R2, you can reverse replication back to the primary server. When you reverse replication, you can select to use an existing virtual machine to limit the amount of replication that must be transmitted over the network.

    - Migration cancels a test failover that currently runs for a Replica virtual machine and deletes the test virtual machine.
- When you upgrade the primary server, consider the following factors:
    - The Replica server has already been upgraded to Windows Server 2012 R2. If the Replica server has not been upgraded to Windows Server 2012 R2, replication fails until the Replica server is upgraded to Windows Server 2012 R2.
    - Replication continues at the default frequency of 5 minutes, which can be modified if it is required.
    - When you use certificate-based authentication for Hyper-V Replica, after you move the primary virtual machine to a new server, you must update the certificate thumbprint for the virtual machine.

      You can update the certificate thumbprint in the Hyper-V Manager Console by editing the Replication settings of the virtual machine, or you can use the following Windows PowerShell cmdlet, **Set-VMReplication**.

      ```
      Set-VMReplication –VMName <virtual machine name. –
      CertificateThumbprint <thumbprint>
      ```

Hyper-V: Stand-alone Migration

This scenario describes how to migrate a single server running the Hyper-V role in Windows Server 2012 to Windows Server 2012 R2.

Migration options

When you migrate a single server, you have the following migration options available:

- In-place upgrade
- **Cross-version live migration**
- Export and Import (not covered in this guide)

In-place upgrade

This scenario describes how to use the existing hardware that runs the Windows Server 2012 operating system and to perform an in-place upgrade of the operating system to Windows Server

2012 R2. This scenario does not require any additional hardware; however, during the upgrade process, all of the virtual machines must be turned off or be in a saved state.

Notes

- We recommend that you shut down or turn off all of the virtual machines before you upgrade. Virtual machines can be in a saved state during the upgrade, but we do not recommend it. You receive a warning during the upgrade process if any of the virtual machines are in a saved state.
- Before you run an in-place upgrade, we recommend that you back up the management operating system and the virtual machines.

Perform an in-place upgrade

Use the following steps to perform an in-place upgrade.

Note

If Hyper-V Replica has been enabled on any of the virtual machines, we recommend that you upgrade the Replica server first. During the upgrade of the Replica server, the primary server continues to send updates to the Replica server, and you might see warning messages about the health of the replication. After the Replica server has successfully upgraded, the replication should continue normally.

- Log on to the server by using a user account with local Administrator rights.
- Insert media for Windows Server 2012 R2 and run **Setup.exe** if the installation program did not start automatically.
- Review the upgrade report and fix any blocking warning messages.
- After the server running Hyper-V has restarted, confirm that the server running Hyper-V was successfully upgraded.
- Install the latest updates.
- Start each of the virtual machines that were running before the upgrade.
- Confirm that each virtual machine operates as expected.
- Upgrade the integration services for each virtual machine. A restart might be required to complete the integration services update.

Cross-version live migration

The upgrade to a new version of the Windows Server operating system no longer requires downtime of the virtual machines. In Windows Server 2012 R2, live migration has been updated to support the migration of Hyper-V virtual machines in Windows Server 2012 to Hyper-V in Windows Server 2012 R2. If the virtual hard disk (VHD) files are stored on an SMB 3.0 file share, you must only move the virtual machine, but not the storage.

This scenario requires additional hardware for a destination server. Ensure that the destination server has the capacity to run the virtual machines that you are currently running and has room for future expansion.

Use the following steps to move a virtual machine from Windows Server 2012 to Windows Server 2012 R2.

Prepare the new server hardware

1. Install Windows Server 2012 R2 on the new server hardware.
2. Install the Hyper-V role on the server.
3. Configure the following Hyper-V settings, for example:
   - The default location for virtual hard disks and virtual machine configuration files.
   - NUMA settings.
   - Live migration settings. Even if live migration was not previously configured, you must enable and configure live migration on both servers.
   - Replication settings if Hyper-V Replica is used. If certificate-based authentication is configured, an appropriate certificate must be installed on the new server.
   - Virtual switches.
   - **Hyper-V Administrators** local group membership.
4. Install the latest updates.

Move a virtual machine from Hyper-V in Windows Server 2012 to Windows Server 2012 R2

In this section, you move a virtual machine from Hyper-V in Windows Server 2012 to Hyper-V in Windows Server 2012 R2.

Perform this procedure on the source server running Hyper-V in Windows Server 2012.

To move the virtual machine to Hyper-V in Windows Server 2012 R2

1. On the **source server** running Hyper-V in Windows Server 2012, open the Hyper-V Manager Console, and then select the virtual machine that you want to move.
2. From the **Actions** pane, click **Move**. This action opens the **Move Wizard**.
   a. On the **Choose Move Type** page, select **Move the virtual machine**.
   b. On the **Specify Destination Computer**, specify the name or server that is running Windows Server 2012 R2.
   c. On the **Choose Move Options** page, select **Move only the virtual machine**.

   You can also use the Windows PowerShell cmdlet **Move-VM**. The following example shows a virtual machine *test VM* that is moved to a remote computer *NewServer* where the virtual machine is stored on an SMB share.

   ```
   PS C:\> Move-VM –Name "Test VM" -DestinationHost NewServer
   ```

Modify the Hyper-V Replica settings

Note

Perform the following procedure on the primary server after moving a virtual machine on the Replica server.

[Optional] To modify Hyper-V Replica settings

1. On the primary server, open the Hyper-V Manager Console, and then select the virtual machine whose Replica virtual machine was just moved.
2. Right-click the virtual machine to select **Settings**.
3. Select **Replication** and update the value for **Replica server** with the name of the destination Replica server.
4. Confirm that replication has successfully started.

   You can also use the **Set-VMReplication** cmdlet to update the name of the Replica server.

Verify that the virtual machine runs correctly

This procedure describes how to confirm that the virtual machine that was moved runs correctly on the destination server running Hyper-V in Windows Server 2012 R2.

Note

Skip this step when you move a virtual machine on a Replica server. Replica virtual machines are in an off state until the virtual machine is failed over by the administrator.

To verify that virtual machine runs correctly

1. Open the Hyper-V Manager Console on the destination server.
